It looks as if urgency were to be given to the big suit of the Government against the American Bell Telephone Company. Mr. Jenks, the Assistant-Attorney-General, has, on application, caused a mandate to be issued by the United States Supreme Court to the Massachusetts Circuit Court, informing the latter tribunal of the decision against the Telephone Company. It appears that the mandate of the Court would, in the ordinary routine, have been issued after the February recess; but in order to hasten the trial of the case on its merits, it has now been specially issued. With regard to the object of the Government in the matter, Mr. Jefferson Chandler, of St. Louis, one of its counsel, is reported to have said that, in spite of this urging of matters, he does not think they can get to the trial point under six months. In that event the question, if tried at all, would be tried under the direction of the new Attorney-General of the Republican Administration. The general expectation is, from the fact that the litigation has been one of the scandals of the Democratic Administration, that the incoming Republican President and Cabinet will care to have nothing whatever to do with it, and will drop it at once. No declaration has yet been made as to the probable policy of President Harrison in regard to this question; but it is safe to assume that he will be well pleased to let the case alone, even although he should be liable to the allegation of having been influenced by the Telephone Company.

The city of Boston is just now interested in an agitation which has been started by some citizens to reduce the cost of electric lighting. There has been quite a controversy in the newspapers on the subject, and it would appear from the electrical papers this week that one of the main points of the agitators has been the lessened cost of the carbons. It has been incidentally brought out that when the company that now does the lighting had its contract from the city in 1882 carbons were costing at the rate of $120 a thousand, or sixpence each. Now, however, carbons are down to from $10 to $15 a thousand, and the Bostonians think they ought to have the whole benefit of that reduction. But, as has been pointed out here, the price of carbon is only one element in the matter. For instance, since 1882 there has been a tremendous jump in the copper market, and the consequence is that conductors, looking at the copper alone, cost more than they did five years ago. In addition to that, the conductors have to be more fully and perfectly insulated, and there again additional expense comes in; while, in many instances, the companies are put to the further cost of labour in regard to underground experiments, which but too often prove failures. Hence it is evident that there is a great deal more to be taken into consideration than the mere current market value of the carbon points to trim the lamps with. Reference has also been made by the leaders in the Boston movement to the fact that in 1887 several extraordinary low bids were made for electric lighting in New York, but Mr. Gilbert, the president of the Boston Company, points out that not only was that a season of merciless competition, but that several companies then bidding had an existence only on paper, so that the companies in possession of the field took low contracts, not because they were fair, but because they were at that time vital to their existence. Mr. Gilbert might have added, too, that those low contracts in New York lasted but a year, since when prices have been much better, and are likely to go even higher. I mention this fact because it is typical of movements that have been going on in other cities, and which are, in a way, expressive of the general desire to obtain more electric lighting without paying more for it. In several cases the cities have themselves been conducting an investigation into the matter, and have convinced themselves that it would be better for them to buy plants of their own and run them. There would undoubtedly be shown a saving to any city by the adoption of such a plan, because the city would be cutting off the profit which the company naturally expects in its investment; but, on the other hand, I am not aware that it has yet been found on the whole, and in the long run, in this country, wise for a city to conduct such industrial enterprises, which hardly seem to come within the same catagory as water supply or the building of harbours, and are greatly liable to the adverse influences of political picking and stealing.

A rather interesting little article appears in one of the papers this week on the subject of stock tickers and their patrons. As you are probably aware the ticker is a great institution in this city. The average "down town" New York broker does not seem happy unless he is within earshot of the little instrument, and one of his favourite amusements is hanging on to the end of the tape as it slowly reels off, or else drawing out a few miles of it from the basket, and tangling himself up in it. The article I refer to mentions an amusing case of a Wall-street devotee who had been in the habit of hanging over the tape all day long, and who, as the result, was soon worried into a state of nervous prostration. He was placed by the doctors in a quiet room at his hotel, but did not get better, and was afterwards moved again to an even quieter asylum. But there his nervous ailment instead of slackening became greater, and all the doctor's efforts at cure were futile. One day, however, it struck the doctor that there was always a pretty big bank of pillows at the end of the bed, and he began to re-arrange them, whereupon the patient protested vigorously. The pillows were tumbled off, however, and there was revealed to view, clicking away, a regular everyday ticker. It had been smuggled into the room and set going for the special benefit of the invalid? There are now some 3,000 of these tickers in New York city alone, and an idea of the work that they do may be formed from the fact that the business of the Stock Exchange, which constitutes the bulk of their reports, will often run to three or four hundred thousand shares a day, so that an operator, to get the quotations promptly from the floor and send them out to the main ticker office, will have to be capable of receiving and sending the number of shares and prices of from twelve to fifteen different shares of stock in one minute, which means making legible characters at the rate of 115 every 60 seconds during the busy hours of the day. The privilege of reporting on the stock, produce, cotton, and other exchanges has been warmly contested for. For a long time the Stock Exchange work was considered a perquisite of the Gold and Stock Telegraph Company, which is owned by the Western Union Company; but of late years the Commercial Telegram Company has obtained a footing, and under the decision of the United States Supreme Court, just rendered, the Stock Exchange is enjoined from expelling from its floor the Commercial Telegram Company, so that if one set of tickers is thrown out the other must go too. It has been proposed three or four times on the exchanges to keep the quotations made there as private as possible, but it is not likely that this will ever become law, as the public is much too deeply interested in the current prices of stocks to hand over its money in that way to the Star Chamber body. As a general thing it may be said that the reporting of the exchanges is very well done, although now and then a little slip occurs, such as that which happened a few days ago on the Chicago Board of Trade, when the inaccurate statement of certain figures affecting the grain market caused quite a panic for a few hours, and made a considerable difference in the bank balance of several members.

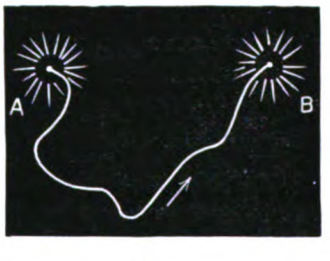
I notice a brisk discussion going on in your own columns, and those of your well-known contemporary, with regard to storage-battery cars, the use of overhead lines, and Mr. Sprague's position in relation to both methods of operating street railways. While Mr. Sprague is very enthusiastic with regard to the future of storage batteries, I do not think that anyone who has ever heard him speak on the subject would hesitate to say that at present he is an ardent advocate of and believer in the overhead line method of operation. In fact, all the work that his company is doing at the present time is by overhead wires, and the new contracts provide, it is said, for the same method. At the same time, the storage method is looked upon as the ideal to be aimed at; and, even if we cannot yet reach it, a great many efforts are being made, as we say, to "get there." The Julien cars are now running regularly in this city, creating a most favourable impression, and being very well patronised by the public. This week news comes from the Pacific Slope of the starting of a new road there, which is to be operated by storage batteries. The first car put upon the road has been built by the Electric Car Company of America with twin Reckenzaun motors of four horse-power each, developing up to eight horse-power, and with 80 cells from the Electrical Accumulator Company (E.P.S.). It is reported to be the intention of the Electrical Accumulator Company to start a factory on the Pacific Slope for the construction of its batteries, and colour is given to the report from the fact that Mr. Frederick Reckenzaun, from the Newark factory, is already out there. Meanwhile, in three or four cities ordinances have been passed to the effect that if electricity be resorted to, only storage batteries shall be used, and New Orleans is one of these places. Perhaps New Orleans furnishes as good an opportunity as any in this country for the adoption of the storage system. The city and the country around is as flat as a billiard table for miles and miles, and the main streets outside of the old French quarter are generally very straight, running long distances without a bend. The people interested in the New Orleans project are already connected with electrical pursuits, and are strong in various ways, so that something is likely to be accomplished in that quarter.

CORRESPONDENCE.

THE MUTUAL ACTION OF A PAIR OF RATIONAL CURRENT ELEMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Strictly speaking, there is no such thing, from the Maxwellian point of view, as mutual action between current elements. Suppose, however, we have the well-known Ampèrian field of magnetic force usually ascribed to a current element at one place, and a similar one centred at another place, it is clear that the forces concerned are quite definite, according to Maxwell's theory. The electric current of such an arrangement is closed. It is related to the nominal current, viz., in the element, in the same way as the induction of an elementary magnet is related to its magnetic moment, as regards the space-distribution. We may term the arrangement a rational current element. If we take any number of equal rational current elements and put them in line, with opposite poles in contact, only the terminal poles are left free, so that the current consists of a straight or curved line or tube of current, joining two points, A and B, with



external continuity produced by means of an equal current diverging from the positive pole B in all directions uniformly, and converging to the negative pole A in a similar manner. Of course the tubes of current from B join on to those at A, and are curved; but it would only confuse matters to super-impose the two systems of polar current, which are much better kept separate. The rational current element itself is to be regarded as an infinitely small volume with a uniform current distributed in it, *and* of the complementary currents from and to the poles. The moment is current-density multiplied by volume, ignoring the complementary currents altogether for the moment. What the actual current in the element may be does not matter much. It depends on the shape of the element. Thus, if spherical, the nominal strength of current, reckoned by its moment, is half as great again as the real, owing to the back action of the polar current. We need only consider the moment, which is fully representative of the external magnetic field, which, it should be remembered, is that due to the moment, according to Ampère's rule. To further illustrate, take the case of a charge, q, moving at speed u, small compared with that of light,* through a dielectric. The moment is qu; the magnetic force is qu/r^2 at distance r in the equatorial plane,

* See my letter in *The Electrician*, November 23, 1888, p. 84.

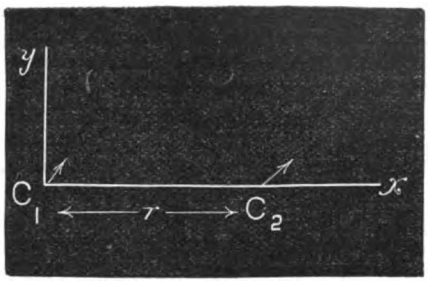
Digitized by Google

and elsewhere proportional to the cosine of the latitude. The actual state of things in the element may require very complex calculations to discover, but is of little importance.

The mutual action of two German or irrational current elements is indeterminate, and so we get a large number of so-called theories of electrodynamics. But the mutual action of a pair of rational current elements is a legitimate subject of inquiry, is determinate, and does not involve any action at a distance. The quantity from which, by dynamical methods, we derive the forces (mechanical) on the elements is the mutual magnetic energy (leaving out of consideration the electrostatic force, if any), that part of the magnetic energy due to both rational current elements. If I have correctly calculated it, the mutual energy M of elements whose distance apart is r, in the medium of inductivity μ, is expressed by

$$M = \frac{\mu}{2r}\left(2u_1v_1 + u_2v_2 + u_3v_3\right)$$

where u_1,u_2,u_3 are the components of C_1, the moment of the first element, and v_1,v_2,v_3 those of the second, C_2, on the understanding that the axis of x is the line joining the elements, whilst the y and z axes are, as usual, perpendicular to it and to each other. In another form



$$M = \mu\left(\frac{\cos\epsilon}{r} + \frac{1}{2}\frac{d^2r}{ds_1ds_2}\right)C_1C_2,$$

where ϵ is the inclination of the elements C_1 and C_2 parallel to s_1 and s_2.

If we substitute for r, in the differential coefficient, an arbitrary function R, we obtain the most general formula which will lead to Neumann's result for closed circuits. It is this R that is, by German methods, indeterminate. Rationalise the elements and we fix it to be r. Clausius took $R = 0$, I believe. It does not matter at all, so far as closed circuits are concerned, what formula we use, provided Neumann's result is complied with; but it is interesting to observe that the problem as stated by me has no uncertainty about it (except any possible working errors) and makes M definite, whilst it is not a mere mathematical abstraction (*i.e.*, the problem), but representative of (under certain circumstances) a reality. It is for these reasons that I mention the matter. For, as a matter of fact, I believe the whole method is fundamentally wrong, and of little practical service in the investigation of electro-magnetism from the physical side, *i.e.*, with propagation in time through a medium. What does it matter about the current elements? They are *not in it*. Still, such formulæ are sometimes of service, as, for instance, in the calculation of inductances.

It has been stated, on no less authority than that of the great Maxwell, that Ampère's law of force between a pair of current elements is the cardinal formula of electrodynamics. If so, should we not be always using it? Do we *ever* use it? Did Maxwell, in his treatise? Surely there is some mistake. I do not in the least mean to rob Ampère of the credit of being the father of electrodynamics; I would only transfer the name of cardinal formula to another due to him, expressing the mechanical force on an element of a conductor supporting current in any magnetic field; the vector product of current and induction. There is something real about it; it is not like his force between a pair of unclosed elements; it is fundamental; and, as everybody knows, it is in continual use, either actually or virtually (through electromotive force) both by theoretical and practical men.—Yours, &c.,

November 25, 1888. OLIVER HEAVISIDE.

ELECTRIC TRACTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Before replying fully to Mr. T. Parker's gratuitous criticisms on my work I desire it to be known that I have no grudge against this gentleman, and that I wish him and the company he is connected with every success in the difficult task they have undertaken in connection with electric traction. I have never had the pleasure of meeting Mr. Parker, and I feel sure that he would not have made the attack contained in your last issue had he studied the subject carefully, and had he considered the motives which led me to adopt certain principles. And I write this letter in the hope of dispelling erroneous notions among those of your readers who have not had opportunities of following up the various modes of arriving at the same ends which have from time to time been suggested by different workers.

The reasons why I have adopted a particular form of battery plate have been so fully and clearly stated in your issue of December 14th that I need not refer to them here; but, with regard to Mr. Parker's statement about Dr. Frankland's plate, I wish to say that I have been experimenting quite two years prior to applying for a patent on this method of constructing electrodes. Dr. Frankland applied for a similar patent nearly three months after me. I am satisfied, however, that Dr. Frankland had not the slightest idea of infringing. It appeared from some correspondence in the *Electrical Review* some time last year, that Mr. Epstein, in Germany, has also been working in a similar direction, and I am not at all surprised to hear of others who started in the same groove. If I have arrived at advantageous and definite commercial results before anyone else it was due to my own efforts, and to the assistance of those immediately connected with my business, and I disclaim all knowledge from any extraneous source. Whilst the broad idea of casting plates in the manner described required no great inventive faculties, the details gone through before we arrived at maximum useful effects with my traction cells were attended with an immense amount of trouble and expense. This truth Mr. Parker will be the first to admit and appreciate.

When giving his opinion about the employment of two motors in one car, Mr. Parker says, "In watching numerous experiments, we have found this has a great tendency for the cars to leave the rails." I do not see how one, two or more *motors* can influence the harmony between wheel flanges and rails. Several of the most experienced American firms have lately adopted my plan of using two motors on electric cars, for obvious reasons; four driving wheels must give better results than two, especially on grades. Much could be written about this branch of the subject, but I do not wish to encroach too far upon your valuable space, and many engineers are aware of the advantages of multiple driving wheels.

Referring to Mr. Parker's statement on the relative efficiency of two small motors against one of double the weight and power, I would suggest an experiment which will convince him that there is not much difference, and the advantages of double motors are numerous. Motors for self-propelled cars, if intended to work underneath the floor, have to be made of limited dimensions—that is to say, they must not have much depth, 10in. to 14in. at the most—although they may be of considerable length parallel to the axis of the armature. If we take, for instance, the iron carcase of a 16 horse-power tramcar motor, and cut the same in two halves, and if these halves are wound with the same section of wire and the same number of turns which were intended for the whole, there will be little difference in efficiency. The torque must be practically the same, and I limit this assertion to the above example of making two motors out of the iron and copper of one double the length and of equal cross-section. Continuing the sentence my critic says, "And they have double the liability to derangement" Now, if there is any "liability to derangement," then two motors are safer than one, because the probability is that both do not get deranged at the same moment, and one machine can drag the car home with a little extra exertion, provided that it is built with that margin which an experienced man will allow in designs of tramcar motors.

Mr. Parker thinks that "the mechanical mode of driving in

Digitized by Google

this (my) car will not commend itself to mechanical engineers." I am accustomed to such remarks; many others who have not been sufficiently educated in this subject have ridiculed it. My experience in mechanical engineering extends over twenty-four years. The last eight years of this period I have devoted to electrical engineering, especially electric traction. It is more than four years now since I employed worm-gearing of a suitable shape for the purpose under consideration, and I took it up as a last resource after trying other kinds of gearing. I notice that several engineers have recently obtained good results with chains of a novel construction, and with spur-gearing of excellent design, but I am so satisfied with the working of worm-gear that I would not abandon it until something very much better can be provided.

The *commercial* success of electric traction does not depend upon a few per cent. more or less of efficiency in one particular part of the propelling apparatus, nor does it mainly depend upon the amount of coal burnt per car mile, but upon the total cost of traction inclusive of repairs and renewals. In addition to questions of economy the commercial success depends in a large measure upon points of convenience and safety, absence of noise and vibration, compactness, non-liability to break-downs, simplicity of management, and the like. I have not yet seen any mechanical gear entirely suitable for tramcars which has given 10 per cent. more efficiency than my gearing, and I venture to say that after several years' continuous use the total cost of traction with worm-gear, all other things being equal, will be found the cheapest.

Mr. Parker is most anxious to belittle every one of my efforts, and he says in conclusion, "The method of charging the field connections, so as to be able to run with a varying field in the motor, seems an ingenious contrivance for emptying the batteries, without obtaining the energy in the form of work upon the car." One of the nicest problems in connection with storage battery cars is the starting, the frequent necessity of overcoming the inertia of a heavy mass. In order to do this effectually the motors must be able to exert a great initial pull. This can only be obtained by the statical effect of a powerful field-magnet excited by a great number of ampere-turns. In order to keep the starting current within safe limits the turns of wire must be numerous, involving a considerable resistance. As soon as the motor has acquired a certain speed, and with it a counter E.M.F., this extra resistance is no longer wanted. Therefore, I divide the field coils of my series-wound motors into several equal parts and join all their ends in series when starting, *i.e.*, when I want the greatest effort with a reasonable current. Under these circumstances the apparatus gives the highest efficiency as an electro-magnet, intended to produce its maximum statical effect upon the armature. When I want it to work efficiently as a motor, with a maximum dynamic effect, then I join the ends of the said coils (automatically by the movement of a handle) so as to obtain one-quarter the resistance, which gives the usual car-speed with the most economical current without saturating the iron cores. If I want more power for mounting a steep grade at good speed I join the armatures in parallel, then the current is greater and the iron saturated; but I have still practically the same efficiency. Other combinations can be effected, but I need not enumerate them. In *all* cases all the wire is active, and the sectional area of the conductors adjusts itself to the current density. Of course the windings must be such that the efficiency is high under all circumstances; the important thing is to maintain certain relations between the conditions of electric supply and the speed and turning moment of the motor, and these conditions are obtained without any serious compromise. The cells in my cars are always all in series. I have tried other methods of varying the power by coupling cells in groups, by inserting artificial resistances between the cells and motors, and by using a variable speed gear; but none of these satisfied me as well as the above method, for reasons which I will not state here, because it is not in my right to ridicule the schemes of my rivals. Moreover, I am always open to conviction, always ready to learn, and I would rejoice to see other men successfully working in a different direction. I think it bad taste to run down in newspapers the work of competitors. We get very little encouragement from the public at large, the prejudices to be overcome are very great, and there is no need of the same being augmented by those most interested in the development of electric tramways.

I should like to see competitive public trials with electric cars made for the purpose of determining the merits of each kind or system, and the editors of our excellent engineering and electrical journals to be judges. Such a competition would save capitalists from plunging into immature ventures, it would draw public attention to a new and important industry, and it would speedily weed out sickly schemes unfit for existence, or hasten the cure of those not constitutionally weak, but merely suffering through disorders brought about by want of experience.—Yours, &c.,

A. Reckenzaun.

London, December 22, 1888.

THE BERNERS-STREET MISHAP.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I was very much surprised to see a statement in an editorial note in your last issue that the burning of a telephone bell in Berners-street is attributed to the end of a broken telephone wire having fallen across a line belonging to the Exchange Telegraph Company, and the sparks which flew across the room, and the shock felt by the lineman, were caused by the Exchange Telegraph Company's current, and had nothing to do with the electric-light wire.

I have referred to the original letter in the *Standard* which first drew attention to this circumstance, and find that the great noise which threw off the gong of the telephone occurred in the night of Friday last, and the smell of burning flame bursting from the wire, sparks flying across the room, &c., occurred at about 11 a.m. on Saturday.

We have but one wire in that locality, and the last message of the day was transmitted at 3 p.m. on Friday, and on Saturday nothing was transmitted between the hours of 8 a.m. and 12:30 p.m., and no contact with another source of electricity occurred.

I think, Sir, that you should have ascertained the grounds, if any, for such a serious statement before publishing it as a fact. The current we employ is incapable of producing the effects described, which are no doubt due to the electric-light cable, which is so imperfectly secured that it has dropped upon our wire three times, without, however, doing any injury to our apparatus, owing to the protecting covering upon our wires.—Yours, &c.,

F. Higgins.

[In the paragraph of which our correspondent complains we stated in perfectly unmistakable terms that the destruction of the telephone was due to a cross with an electric-light wire. But since the telephone wire was melted at the point where the contact occurred, and the end fell over another wire, it is clear that the "sparks," which were seen when the lineman opened the instrument did not come from the electric-light circuit. We further hinted our belief that, whatever may have really happened at this moment, the description in the *Standard* was grossly exaggerated. We understand that the lineman denies that the shock which he experienced was "sufficient to make him let go the pliers," and the "sparks flying across the room" was also a palpable exaggeration. So that whether it was or was not an Exchange Telegraph Company's wire on which the telephone wire had fallen seemed to be a point of no importance whatever. However, if our information was incorrect, we regret to have alluded to the Exchange Company in connection with the affair.—Ed. *E.*]

MR. ATKINSON'S BOOK ON "THE ELEMENTS OF ELECTRIC LIGHTING."

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I am informed by the publisher of my recent work, "The Elements of Electric Lighting," that various English publishers propose to prohibit its sale in England, on the ground that it contains matter appropriated from English electric works published by them.

As I have always had such contempt for plagiarism that I seldom even quote from another writer, preferring to use my

Digitized by Google

own phraseology when adopting the ideas of others, I was much surprised to learn that such a charge had been made, and must infer that it is not possible that any of these gentlemen can have carefully read or examined my book. A charge of theft, literary or otherwise, "cannot be sustained till the property is found in possession of the thief and identified," and the burden of proof rests upon those bringing the charge. My work is before the public, and no one can show a single line which I have appropriated from any other writer except in my summary of installation rules, pages 254 and 255, which I do not claim as my own. I found these rules given in common by different writers, and modified them to suit my purpose.

In my chapter on the storage battery I adopted the theory of Gladstone and Tribe, using my own phraseology, and giving them full credit, both in my introduction and on page 218.

As stated in my introduction, I consulted the works of several different writers mentioned by name, and embodied in my own language, modified by my own ideas, such matter as I found adapted to my use. This I understand to be the privilege of every writer. No scientific writer can claim to be wholly original—his writings are necessarily based on information derived from others, whose ideas have become incorporated into his own body of thought. And as the object of a book like mine is to give the latest and most reliable information obtainable on the subject, and not merely one's own peculiar views, I not only consulted other writers, but made a thorough practical examination of the various kinds of apparatus described and the principles of their operation; visiting factories and inspecting machines and apparatus in the various stages of construction; conversing and corresponding with inventors and manufacturers; examining patents, and by every possible means seeking full and accurate information on every point.

My illustrations were obtained from various sources; some from books, pamphlets, and periodicals, others from cuts lent me by patentees and manufacturers, and others from my own drawings; most of those from outside sources requiring modification to adapt them to my use. Some of these illustrations are the same as those found in English books, and yet even these are, in many instances, identical with those from cuts lent me by American manufacturers, while others are found in common in various electric works, so that I had no evidence that any of those copied from English works were from original drawings designed for any particular book; indeed, the authors themselves acknowledge that their illustrations were in part obtained from outside sources. Hence I have only followed the common practice of others by copying such illustrations as I found adapted to my use, for which, in my introduction, I have given full credit.

English electric books have had a large circulation in the United States, and common courtesy would seem to require that my book should have the same opportunity for circulation on its merits in England.—Yours, &c., PHILIP ATKINSON.

COMPANIES' MEETINGS.

Metropolitan Electric Supply Company (Limited).

An extraordinary general meeting of the shareholders of this Company was held at Winchester House, Old Broad-street, on Friday, December 21st, 1888, under the presidency of Sir John Pender, K.C.M.G.

The CHAIRMAN, in opening the proceedings, said: Gentlemen, the Secretary will read the notice convening this meeting.

The SECRETARY (Mr. E. Cunliffe Owen) having read the notice,

The CHAIRMAN said: Gentlemen, we have called you together to-day for two purposes—first, to inform you as to the progress the Company has made since August last and its present position and prospects; and, secondly, to put before you a resolution approving an agreement made by the Board, under the power of the Articles of Association, to vary the original agreement entered into between this Company and the Whitehall Company for the purchase of the property and the undertaking of the Whitehall Company. And first, with respect to the work done. You are aware that the Company took over from the Whitehall Company the important works and installation which the latter had established at Whitehall Avenue. That station, which has about 10,000-light capacity, was opened on the 5th October last, and the Directors had hoped that the full capacity of lighting would be taken up by customers in seven or eight months. Instead of this, the full capacity of the station is taken up already. In about two months orders were booked for nearly 9,000 lamps, and the mains for connecting them are being laid as fast as possible. The Avenue Theatre, the Hotel Victoria in Northumberland Avenue, and other places have been lighted for some time, and the managers have written expressing their satisfaction with the supply, and among the more recent contracts secured to be worked from the Whitehall station are the Grand Hotel, Messrs. Hampton's large furniture warehouses in Pall Mall, St. Martin's Church, and other places. The Company's mains are being laid underground throughout the whole of the Charing-cross district, and have already been laid across Northumberland-avenue, West Strand, and Trafalgar-square, without causing any appreciable interruption to the traffic. Mr. Gordon informs me that the guaranteed revenue from the contracts made and to be carried on from the Whitehall works is £13,500 a year, and that other contracts, expected to be completed in a few days, will be another £1,000 making altogether £14,500. The working expenses, including rent, salaries, wages, and 10 per cent. for depreciation, are estimated at £6,000, leaving a profit of £8,500 a year on these installations, which, I think, is fairly satisfactory, seeing that the capital represented by these works is not much over £40,000. As to the Sardinia-street works, the buildings in Sardinia-street are in hand, and a large body of men are employed on them. We have put up a map here in which you see the Sardinia-street station. I may say without any hesitation or fear of contradiction that that station will be one of the most important in London. It embraces the important residential property about Bloomsbury, the shops, hotels, and large restaurants in Holborn, the important newspaper, publishing and printing establishments about Fleet-street, and the banks, shops, and numerous buildings in the East Strand district. That station will, I think, have altogether 50,000 lights, and so far as we can see now and judge from the inquiries that are made, it will not be a long time after the installation is completed before that will be fully occupied; and if the results upon the 50,000 lights are at all in proportion to what we now see from the practical working of the Whitehall works, I think we may congratulate ourselves on being in a position to make very handsome dividends. I may mention that the machinery for this station has been ordered from the Westinghouse Company, and the bulk of it will be delivered in a very short time. The object of ordering this machinery from the Westinghouse Company is this—that they have put down in America 116 installations, all of which have been successful, and the principle we have gone upon—what has been the policy of this Company, because we have not been idle during the last six months—has been to take the very best thing in existence, and to utilise it for our purposes. This American system is considered almost perfect, as far as it has gone. We are inviting tenders from English contractors for another installation, and so we shall work one against the other, and we shall have the full advantage of what I may call contractors' competition. I think the result of that will be to give us the best thing of the kind up to the present moment. I do not mean to say that in electricity, as in other things, there is not very great progress. You will see that that is the case when I tell you that it is scarcely ten years ago since electric lighting was a laboratory experiment, whereas it is now almost becoming universal. I may go further and say this: It is not more than twenty-five years since submarine telegraphy was first introduced, and there is now £40,000,000 sterling in the bottom of the sea, the major portion of it paying a fair dividend. That shows that we do not know to what extent electricity can be carried; but, so far as we have gone, it seems that the electric light is to be the light of the future. I have no hesitation in saying, if you look at the prospectus we put before you—it was based on a good deal of experience—you will find that what we said in regard to the American installations ought to be thoroughly borne out also in regard to English installations. The Company also took over from the Whitehall Company the extensive and valuable property for electric lighting purposes, the Waterloo Bridge Wharf, which is admirably adapted for supplying the whole of the Strand district, and which can take the machinery required for working 150,000 lamps. That, I think, will be perhaps the largest installation in our system. I want you to understand that we have not gone, in the slightest degree, upon a speculative or experimental policy. We are laying down installations which we know will be successful, so far as the mechanical part of them is concerned, and we believe that the light will be fully taken up by the public; and, therefore, I think we are not over sanguine in looking forward to very successful results. That installation is one which, I hope, will, before another year is out, be in active operation. We know that there are very formidable competitors in the market at the present moment. I greatly admire the enterprise of the Grosvenor Gallery combination, the gentlemen connected with which are of the highest eminence. They have great practical scientific knowledge among them, but they are trying the biggest experiment ever tried in electric lighting, so I am informed by scientific men. I hope their experiments may be successful. I like to see these great efforts of science successful, and I believe if this experiment is successful it will be a very remarkable step in electrical progress. We have been more cautious, probably more prudent. We are not putting all our eggs in one basket. We are so putting our different installations that we can work them collectively or separately; consequently we are not likely to break down as a whole. You can see the object of that, and we have acted upon the advice of our eminent scientific advisers. Therefore, every installation of ours will stand alone, but every installation will stand shoulder to shoulder with its neighbouring installation if so required. Since August last (I have said that we have not been idle) the Directors have secured several other sites for works. One is Greenmore Wharf, a large wharf adjoining Southwark Bridge, which is suited for lighting the City of London proper. We have also obtained a site in South-mews, Manchester-square, for the Marylebone district. Negotiations are proceeding for other sites. The specifications for the machinery for the Greenmore Wharf have been sent out, and tenders are expected in a week or two from various responsible English firms. Specifications for the other sites will go out immediately. With regard to the Strand district, the Company has secured a monopoly of the lighting of the new Salisbury Estate, consisting of Salisbury and Cecil streets, for the ground of which alone a sum of £200,000 has recently been paid. That will probably be one of the most remarkable improvements in London. I cannot say much more with regard to our prospects. In the summer it was said they were encouraging, and I think if I went over article by article in the prospectus put before you, I could justify every item in it. The second portion of our business to-day I hope will also be satis-

Digitized by Google

factory, because it is very much for the benefit of the Company's interests, though probably not so much to the satisfaction of others, who have been working for the last two or three years, and who consider themselves very badly paid indeed for their work and property. I may say at once that the short result of what we ask you to confirm to-day is to reduce by just one-half the purchase money payable by the Company for the property and rights which they agreed to take over from the Whitehall Company. The price is reduced from £79,000, the sum named in the prospectus as having been fixed by the vendors, the Whitehall Company, to the very modest sum of £40,000. This, you will see, is practically reducing the purchase money by one-half, and I am sure every shareholder in this Company will be glad that this reduction is to be made. The vendors are willing to make the reduction, though they are by no means satisfied with the decision that Sir Frederick Bramwell and Sir Whittaker Ellis have arrived at with respect to the value of the property. It was, of course, to be expected that the vendors would take a more favourable view of their undertaking than what I may call cold-blooded but very experienced gentlemen who sat down to value what was placed before them. The vendors made their arrangements with the Company at a time when there were really no shareholders but themselves and their friends in the Company. No man could then, nor can even now, estimate absolutely what is the value of the undertaking we have purchased. I have told you to-day of our prospects. Probably a year or two hence our stock may be worth twice or thrice what it is to-day, so you see how difficult it is to value a thing which has not been fully realised. Therefore, in this valuation, though it is not so stated, probably nothing has been taken into consideration as to the prospective value of the Company. I do not know what was in the minds of the valuers, and they have, perhaps, wisely given no reason for their decision, but from the course of inquiries which they have made very carefully in respect to the properties actually transferred I have no doubt they have omitted from their calculations these elements of future value which the vendors not unreasonably considered so important. I may add that the vendors would be perfectly willing to take back their properties if the Company did not desire to go on with the purchase; but I believe I am right in saying that every member of the Board is convinced that the property is well worth, and more than worth, the sum we have now decided to pay for it. One other matter ought also to be mentioned, that is with respect to the provisional order which the Board of Trade had granted before the prospectus was issued. This provisional order gave to the Company valuable rights over the parish of St. James's, Westminster, and St. Martin's-in-the-Fields; and when the Duke of Buckingham, as Chairman of Committees of the House of Lords, refused to suspend the standing order which prevented the second reading of the Government Bill to confirm that provisional order, the Board of Trade promised to use their good offices to support a private Bill to enable the Company to secure the confirmation of that provisional order in the next session. The loss of this provisional order, in the sense I have mentioned, occurred between the time when the agreement was made and the prospectus prepared and the date of its actual issue, and I think the valuers must have made a large reduction from the original price on account of the unfortunate slip, which was occasioned by no fault of the promoters but through the delays in Parliament. When the prospectus was issued, and the shares were so readily and so largely subscribed, and so many new shareholders came into the Company, the Directors sat down to consider the position and the course they should take in consequence of the changes which had occurred, and they came to the conclusion that there should be, in the interests of all parties concerned, an independent valuation of the property which the Company was to purchase. Several of the Directors were themselves interested in the properties which had been acquired and were to be sold by the Whitehall Company, and this made it the more necessary that such a valuation should be taken. The South Metropolitan Company was threatened with opposition by the Whitehall Company, and it was really this that brought about the combination of the two parties, one represented by Sir George Elliot and his friends, who had taken a deep interest in this question, and the other by Mr. Balfour and his friends, who had invested largely in the Whitehall Court enterprise, and who had founded the Whitehall Electric Company. The agreement referred to in the circular, which has been sent to you, dated 12th December, 1888, will now be read to you by the solicitor. It has been made especially under power of the Articles of Association, which contain an important clause authorising this being done. The solicitor will now read the agreement.

The SOLICITOR (Mr. Burt): Mr. Chairman and gentlemen, the clause in the Articles of Association is as follows:—

"The Board may, with or without variation, carry into effect on behalf "of the Company, the agreement between the Whitehall Electric Supply "Company (Limited) of the one part, and this Company of the other part, "by which the Whitehall Company, for the consideration therein men-"tioned, agrees to convey and assign to the Company all the property and "rights as in the said agreement more particularly mentioned."

That agreement is annexed to these Articles of Association, and I suppose is in the hands of the shareholders; and the agreement which you are called upon to confirm to-day is as follows. [Mr. Burt then read the agreement.] That is signed, and there is also an endorsement upon it signed by Mr. Verity. [The endorsement was read.]

The CHAIRMAN: Gentlemen, I will put this resolution, and after I have put it, if any gentleman has any remarks to make, or questions to ask, I shall be very glad to answer him to the best of my ability. The resolution is as follows:—

"*Resolved that the agreement dated the 12th December, 1888, made between the Board of Directors of the Company of the first part, and Sir John Pender, Sir George Elliot, Joseph Charles Parkinson, Esq., and the Whitehall Electric Supply Company (Limited) of the second part, for varying the agreement dated the 17th July, 1888, referred to in the Articles of Association (Clause 6), and made between the South Metropolitan Electric Supply Company of the one part and the Whitehall Electric Supply Company (Limited) of the other part, by which the said Whitehall Company, for the consideration therein mentioned, agreed to convey and assign to the South Metropolitan Company its undertaking, property, and rights as therein mentioned, be and is hereby confirmed.*"

ALDERMAN SIR R. N. FOWLER, M.P.: I second that.

Mr. DIBLEY: I am sure we must agree with the resolution placed before us by the Board, amending to a large extent the contract made between the Whitehall Company and this Company; and I think before you put the resolution I may express what I believe is the feeling of everyone present when I congratulate the Board on the arrangement they have effected.

The CHAIRMAN: Those in favour of the resolution hold up one hand. To the contrary. Carried unanimously.

Now, gentlemen, we have given you to-day a straightforward statement, and I wish to give you also a little further information, so that on leaving this room you will understand that the gentlemen connected with this enterprise have made up their minds to make it go ahead. We believe the time has come, and that there is a great deal of good useful paying work to be done with electric lighting. This is the further information I will give you. The Company has given notice of a Bill in Parliament to obtain Parliamentary powers to carry on the works for St. James's, Westminster, St. Martin's-in-the-Fields, and Waterloo Bridge, which will include the ground covered by the provisional order which was obtained last summer, but which was not confirmed by Parliament, although the Board of Trade did all in their power to get the Bill passed. Notices have also been given for provisional orders in four districts—Mid-London, North London, South London and West London. It may be that we shall not proceed with all these, but we thought it wise to give the notices, without which we could not proceed. In view of all the works executed and in hand, and what is proposed to be done in the future, the Directors think the prospects of the Company, as put before you to-day, are very encouraging indeed. There is another point. Some people have said to me, "But there are more electric lighting companies in existence than can possibly be required." But the population of this mighty city is five millions of people, and if the electric light is successful (and I believe it must become the light of the future), we shall require to spend thirty-four to thirty-five millions sterling before we can do the work required. Therefore, when I find respectable people—people of high position having money to spend—coming forward to take part in this work I hail them with great satisfaction. There is plenty of good-paying work for us all. As I said before, electricity is yet in its infancy, and the more that science can be brought to bear upon it the more we shall have of this light. The light is doing a great sanitary work, and with its use the air remains pure, and there is less heat. I have not a word to say against gas. I believe that gas, being the essence of heat from coal, has a great deal of work before it, but in another field than that of lighting. Those interested in gas must look to apply it to other purposes. The light of the future is to be the electric light. That finishes the business of the day, gentlemen.

Mr. DIBLEY: I am sure before we part we should all pass a vote of thanks to the Chairman.

A SHAREHOLDER: And the Board?

A SHAREHOLDER: I second that.

Mr. DIBLEY put the resolution, and it was carried unanimously.

The CHAIRMAN: Gentlemen, I thank you on behalf of my colleagues and myself, but I shall receive your approbation with much greater satisfaction after we have paid you a dividend.

The proceedings then terminated.

The London Electric Supply Corporation.

The second ordinary general meeting of this Company was held on Friday at Winchester House, Old Broad-street, E.C., the Earl of Crawford in the chair.

Major CHARLES B. WALLER (the Manager and Secretary) read the following notice convening the meeting, and the report of the Directors was taken as read:—

Notice is given that the second ordinary general meeting of the London Electric Supply Corporation (Limited) will be held on 21st December, and that at such meeting a resolution will be proposed to increase the capital of the Company by the creation of 50,000 new shares of £5 each, to be called Preference shares (with power for the Company to create further new shares to rank in all respects *pari passu* with the said Preference shares, to all of which shares shall be attached the following rights and privileges, viz.:—

"*1. The holders of such Preference shares shall be entitled, out of the profits of each year, to a preferential dividend on the capital for the time being paid up on such shares respectively, at such rate as the Board before the issue thereof shall fix, but without a right to any further participation in profits.*

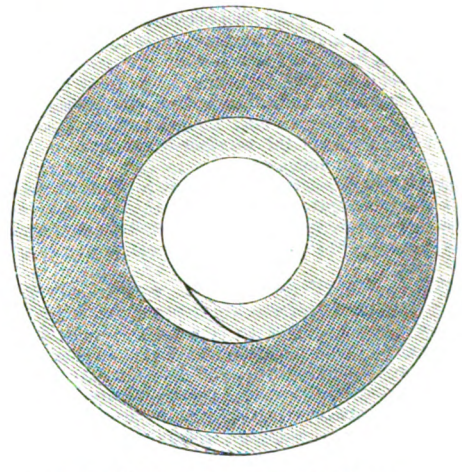
"*2. That in the event of the Company being wound up, the holders of the said Preference shares shall be entitled to have the surplus assets of the Company applied in the first instance in repaying to them the amount paid up on shares held by them respectively, the residue of such surplus assets being divided amongst the holders of the other shares of the Company (hereinafter called Ordinary shares).*

"*3. Any holder of the Preference shares shall be entitled, at any time within five years from the 31st December, 1888, to relinquish the preferential rights of such of the said Preference shares as are held by him and are paid up in full, and thereupon each of such shares shall thereafter become and be Ordinary shares of the Company.*"

Dated the 11th day of December, 1888.

Digitized by Google

The CHAIRMAN said: I think, gentlemen, it would be desirable that I should make a short statement on the report, embodying certain details which are not therein contained. In order to do that I purpose to say a few words, to begin with, on the station which is at present at work belonging to you, which is the station known as the Grosvenor. The Corporation has now been at work since the early part of October, in 1887. At that period they took over the works then existing behind the Grosvenor Gallery, and a set of works, with overhead mains and plant, which had been put down there, and which had lit at that time something like 11,000 lamps. The capability of the Grosvenor Station was originally supposed to be 10,000 lamps running simultaneously. Some time previously to the purchase of the business by the present Corporation the Directors of that Company had spent a considerable sum of money in order to place the dynamos and their engines in a much more advantageous position, in so far as the number of lights they were able to supply simultaneously. They contracted with their engineer to supply dynamos which would be sufficient to give current to 20,000 lights at the same time. It was found when these machines were put into position that the nominal efficiency of 20,000 could be exceeded to the extent of one-third—that is, that the nominal efficiency of two machines, working simultaneously, being 20,000, it would be safe to light 30,000 lamps; therefore, your company got possession of two dynamos capable of giving 30,000 lights. In addition to that there is a system of engines, which is very complete; but, unfortunately, for the present they are not quite sufficiently powerful for the large amount of work which is demanded from those engines. That quantity of power in excess cannot be got from that point, simply and solely because there is not cubic capacity left in the building in which we are working to put down additional machinery. Again, outside your engine room your Company purchased a very large and widely extended system of overhead mains—that is to say, cables, or means of conveying the current from the generating station to the house of the consumer. A good deal has been said, gentlemen, on the question of overhead mains with regard to the safety to the public, which has been called in question. The first danger which has been called in question may be said to be that of a cable breaking, falling down and hitting some person on the head, and killing him or maiming him; the second is, that a man, by touching a main, may get a bad shock, or even be killed. We had confidence that our mains were put up in a proper manner from the commencement; we used the greatest care and the best material we could, and after we had been at work for three years and six months, practically speaking—I should say I am speaking for the old company—but it was rather more than a year after the present Corporation had been at work, the Board of Trade sent to us a letter, saying that they had heard that we were using overhead wires, and they wished to know the factors of safety employed by us in putting these wires up, and what precautions we had taken with regard to giving shocks to persons, and so on. We then said to the Board of Trade: "We shall be very happy to take down the line of wire which has been longest in course of work, place it before you, and allow you to test it in any way you please." The wire was taken down which had been up three years and seven months, it was placed in the yard we use for our stores, the current was put through, and the tension was exactly the same as when it was on the roof, and then one end of that cable was dropped down to earth, technically speaking. Practically it means, supposing the two wires were overhead and got broken and hung to earth, any person touching the wire would not get a shock. We were able to show to the Board of Trade there was not the danger they anticipated. They then said: "Well, your experiment is most successful." The work which had been put up three years and a-half was as good as ever. In October, 1887, your Corporation had about 11,000 lights upon its books; I think I shall best show the shareholders the actual amount of work which has been done since that time by placing before them a series of curves representing the work done in each week. (The Chairman exhibited the drawings referred to and continued): With regard to the curve showing the effect of the foggy weather on the Grosvenor Station,* you will perceive that in the early portion of the day at 11:30 the amount of current—that is the number of lights that were lighted simultaneously—was greater than at any other period during the twenty-four hours of the day. Some little time ago, as you are all aware, it was decided to start another station, as it was found that the demand on the Grosvenor was becoming excessive; we therefore established an installation at Deptford. At the time we got our estimates we were in full confidence that at the present date we should have been supplying a current from that place; but owing to the excessively bad summer and the rainy weather, we found we lost nearly two months, and consequently have been thrown back in that manner. We considered ourselves perfectly justified in taking on customers to be supplied from Deptford. We have been disappointed in that matter, and the result is we have been compelled to take on customers at the Grosvenor until in point of fact we have now 34,000 lights contracted for, and we have been running up to 25,000 simultaneously. Now, it is really the case that it is not desirable to work the Grosvenor engines and boilers to that extent, consequently your Directors have been doing everything in their power, with the consent of consumers, to induce their customers not to use so much current as they were doing. In many cases the consumers have been behaving very considerately, and we have been able to bring the load down to some extent, but many of us would desire to have even more relief. I think I may now pass from the Grosvenor Station, and tell the gentlemen present what we are doing at Deptford. When the present company came into existence it purchased from the old company, or rather took over, a large piece of land of nearly five acres in extent a little to the east of the London Meat Market, next door to the Steam Navigation Company. That land had been lying vacant, and it was admirably adapted for our purposes, especially as it possessed a large river frontage. I hardly think it will be necessary for me to go very fully into this matter, because we have placed in your hands certain documents prepared for the local authorities. The best way that you can, perhaps, get at an idea of the magnitude and scale of these things will be to look at the photographs which I will hand round.* What we have at Deptford to put up to begin with will be a dynamo with its engine capable of giving 25,000 lights simultaneously, and we have every reason to hope that that 25,000-light dynamo will be able to do eventually 30,000 at least, and we shall have another dynamo, also the same size—25,000—which makes 50,000. These will be the first two instruments at work; one will be running, the other will be invariably kept at rest; therefore, at Deptford we shall not have to run everything in order to meet the demand. At Deptford we have a large amount of reserve power, which we consider to be essential to the proper carrying on of a business of this description. As soon as that 25,000-light dynamo is finished we shall have begun erecting the large dynamos, which will be driven by engines of 10,000 horse-power running direct on the dynamo, which will be capable of a simultaneous output of 100,000 lights. Two of those will be put up, and so far the Directors have already ordered the material. The utilisation of those dynamos—that is to say, the current which they produce—is passed up to London by means of copper mains, of which I have a sample here, of a novel construction, and which have done away with all the difficulties which have hitherto been found in electric lighting. The peculiarity of this is that there is one main inside the other (*see* Figure), so that one current passing along kills



Cross Section of Ferranti Conductor.

the effect of the induction of the other. Having got these cables we have to bring the current up so far as London. We knew very well at the time we started this business it would be impossible for us to get Parliamentary sanction for going under the streets at the time which we thought it desirable to commence work, owing to the ordinary formalities of Parliament, and therefore your Board made arrangements with the railway companies in order to obtain their co-operation, as theirs was practically private property, running through different parishes, and therefore not subject to their jurisdiction. Negotiations with the South-Eastern, the London, Brighton and South-Coast, the Chatham and Dover—the Herne Hill Branch—have resulted in our obtaining by means of these three companies way-leaves whereby we can bring the current all the way in an easy and most practical manner into the heart of London. We bring the current across the bridge into Cannon-street, Blackfriars and Charing Cross Stations. Rather before that the Directors entered into arrangements with one of the underground railways for the use of their tunnels. I am not able to say that we have the complete circuit of London at the present moment, because a certain portion is still under negotiation, although the principle is conceded and the agreement practically finished. The only question outstanding is how much per mile we have to pay; I think you may trust your Directors to fight for that being as little as possible. That brings us practically up to London, and our first thing is to carry the mains throughout the town, first by overhead mains, and subsequently, when we obtain provisional orders, by means of taking the streets up and putting mains down underground. In order to give the shareholders an idea of the amount of work which it is our desire to be able to carry through before very long, I brought up a copy of the map we have deposited with the Board of Trade, showing the area for which we have applied for provisional orders. We have asked for powers to deal with the streets in 24 different localities, under the jurisdiction of 24 different local authorities. So far as we have gone through the work, we have given the notice—previous to that we gave notice also for licenses. Well, by the Act of 1882 there were two methods of procedure—one by license, which requires the consent of the local authority and the Board of Trade giving permission for any work to be done; the other method being that of provisional orders, where the Board have power on good reason shown to dispense with the assent of the local authority, and Parliament grants permission to proceed of its own accord. Within the last fortnight the Board of Trade decided it would not exercise the first of these powers, and refused to give licenses to anybody in the metropolis; we are therefore thrown back on the provisional orders. I think the Board of Trade was wise in dealing with such a large question in saying Parliament should have a voice; but, at the same time, I think the Board of Trade would have acted more fairly towards us if they had decided two months earlier, when

Digitized by Google

we should have been spared the expense of applying for the licenses. We have not to-day presented any accounts. The Board of Trade said that all the accounts were to be made up to the 31st December, and were to be presented before the end of March. If we had put it off till that period twelve months would have expired after our last annual meeting, and therefore it was thought desirable to call our shareholders together to hold our meeting at this time, and to get these accounts forward as rapidly as possible, and then present them at another meeting. I am not at all sure it would not be advisable in future to hold another meeting, dating the period when we present the accounts as the period at which we should hold the annual meeting. As regards provisional orders, there is a certain amount of difficulty which must accrue in future, but our business has been placed very nearly in a unique position so far as the commercial business of this country is concerned. We are providing people and doing certain work permissively to our own ends. We are recognised to a certain extent by the Legislature; but, at the same time, we are bound down and hampered and forced to do many things which it may not be to our interest to do. An ordinary business at the commencement will work slowly and will do everything to ensure the largest possible revenue, and is not bound to do more work than will bring in a dividend in the course of any period; but the Act of 1882 gives power to the local authority, after a certain period of time has elapsed, to say, "You shall do certain works for us now, and if you do not do that within six months there comes a certain amount of fine." Well, we have been negotiating with the local authorities to get that time put back as remote as possible. They all wish to say, "You shall be compelled to do that which we ask you to do," so that the local authorities may require us to run mains into places for their own convenience, and require us to light a street, for instance, which would not pay a remunerative sum for the capital outlaid on the mains. There is only one redeeming point in that, and that is the local authority is bound to promise you for three years that they shall take current to the amount of 20 per cent. on the outlay which is incurred; therefore, it may have a certain amount of deterring influence, and it may be doubtful whether we shall be called upon to do this or not; but still we must struggle to have that put back as far as possible. I have tried to get certain vestries to allow it to be two years. I do not think there is anything more with which I need detain the shareholders. I will simply move that the report be adopted, and after that has been seconded I shall be very happy to answer any questions that any gentleman may ask.

SIR COUTTS LINDSEY seconded the motion. He said that until recently he had been the Chairman of the Company, but he had felt much pleasure in resigning in favour of so eminent a scientist and electrician as the Earl of Crawford. The Chairman had explained the nature of the business, the prospects of the future, and he had also explained the difficulties which had arisen in the starting of this business. He believed that the working of the previous Company was very essential to the success of this Corporation. It was the pilot company, and there was no doubt that in the experiments they made they were not always as successful as they might have hoped to have been. At the same time the ultimate result of the sale of their plant to this Corporation was extremely satisfactory. Lord Crawford had passed them a map of the current of each week, and on that map he believed there was registered a certain value; that value was registered by the Government measure—that was the Board of Trade unit—7½d. per Board of Trade unit. That represented what they were entitled to in payment for their current; at the same time they had had very great difficulty in measuring that current properly, and he thought that Lord Crawford did not mention that they were now in possession of a meter which was simply as near perfection as it could be, and that removed one of their greatest difficulties in the future. In the past they had not been able to claim the full value of their output, because they had no meter, and their arrangements were by the year; now, however, any amount of current they supplied they had a voucher for, and that voucher would represent the value to those who consumed it and to the producers. He had only one more observation to make, and that was as to their Board; he thought it was unusual in most companies that a Board should hold such a large number of shares. He thought it might be a satisfaction to them to know that those who were managing their business had an overwhelming stake in its welfare, and that they on their own part, as well as that of the public, were likely to devote the whole of their attention and time to the advancement of this Corporation. In the past the Board had worked with unremitting attention, and when he resigned the chair, which he did recently, he had the pleasure of seeing Lord Crawford take his place; his lordship was a man eminently fitted to perform the duties of the Company, and to safeguard the Company, both from his knowledge of electricity and general capabilities as a man of business. He (the speaker) resigned his seat with pleasure, feeling that his interests and those of the shareholders were perfectly safe (cheers).

Mr. McLEAY asked whether the Metropolitan Electric Supply Company had applied for provisional orders in the same districts as this Company had asked for them.

The CHAIRMAN replied that in a very large number of cases they were the same.

The resolution was then put and carried unanimously.

The CHAIRMAN: We now come to the second portion of our business, referring to the question of the future financial arrangements of the Company. And here it will be necessary for me to refer to what passed at our last general meeting. The capital of the Company consists of 50,000 fully-paid shares of £5 each, 25,000 upon which £4 have been paid, and £180,000 debentures, which it will be in your memory were created by the resolution at our last meeting. Your Directors were empowered at that time to issue those debentures to a member of their Board, Lord Wantage; he has taken up a certain number of the debentures, and the conversion as at that time suggested has been carried out, and before the end of this year the debenture debt of this Company will be wiped out, and the 36,000 shares that Lord Wantage will receive in exchange for these debentures will be actually paid up in full; therefore, I consider we are in a very happy, comfortable position so far as that is concerned. It may seem strange to some of the shareholders that the Directors ask to increase the capital while there is a certain amount of ordinary capital still in hand; they may also ask, "Why do you want any more money at all at present?" With regard to the money I think I shall be able to satisfy you. With regard to the business done at Deptford, we made the most careful estimates we were able to do, and I think our estimate has come out within a very small amount of what actually we consider will be required for paying for it; but in the money so subscribed for this step we did not feel quite certain at the time we had sufficient to do that which we wanted, and therefore, although we may want £30,000 or £40,000 more than we have cash at the present moment, still we are not that amount wrong in the estimate. I estimate we may require £40,000 in order to complete the works and have machinery going capable of giving simultaneously 150,000 lights, and keep 100,000 in reserve. At the present moment we have let it be known to a certain extent that we shall be in certain quarters of London before very long; we have done this in order to let people know we are coming there, and to feel the pulse of the inhabitants of those portions of the metropolis so as to see what customers we are likely to obtain. The response to our circular, I think, would take up the whole supply that we would be able to put down. If we had 150,000 lights ready now we could place them in the course of next week. I think this is a very healthy position to be placed in. In conclusion, the Chairman said that the Directors wanted power to put up sufficient machinery for 200,000 lights more. He said he thought it would be enormously to the advantage of the Corporation to have such power in their hands. He moved a resolution authorising the increase of capital in the manner suggested.

Lord WANTAGE seconded the resolution, which was carried unanimously.

A vote of thanks to the Chairman and Directors terminated the proceedings.

Maxim-Weston Electric Company (Limited).

An extraordinary general meeting of this Company was held at the City Terminus Hotel, Cannon-street, on the 21st inst., Mr. John Marks presiding.

The SECRETARY (Mr. Samuel J. Boyce) having read the notice convening the meeting,

The CHAIRMAN moved the confirmation of the first resolution on the agenda paper, as follows :—

"*That the Maxim-Weston Electric Company (Limited) be wound up voluntarily.*"

Mr. LOUIS SWABY seconded the motion, which was carried with four dissentients.

The CHAIRMAN next moved the confirmation of the following resolution :—

"*That Mr. John Marks, of 113, Great Russell-street, W.C., Mr. J. M. Klenck, 42, Bishopsgate-street Within, E.C., and Mr. Louis Swaby, of 23, Churchfield-road, Ealing, be and they are hereby appointed liquidators for the purpose of such winding up.*"

Mr. HILDYARD seconded the motion.

Mr. ABRAHAMS observed that at the last meeting, on the 3rd December, there were several resolutions tacked on to the foregoing, and as they were not mentioned as coming up forc onfirmation he presumed they were abandoned.

The CHAIRMAN replied that these were the only resolutions which the present meeting was called upon to confirm.

The motion was agreed to with four dissentients.

The meeting was then resolved into a second extraordinary general meeting, and

The SECRETARY having read the notice convening it,

The CHAIRMAN said that since they last met they had been advised by eminent counsel that the terms on which the liquidators should sell to the new company should be embodied in an agreement, a draft of which he would ask the Secretary to read to the meeting.

The SECRETARY accordingly read the document in question.

The CHAIRMAN observed that in drawing up this agreement the counsel who were responsible for it had paid due regard to the rights of all parties interested in the Company. The principal clause in it referred to the fact that there was to be an allotment of one share in the new company for every share held by a member of the old Company, while due provision had been made for the holdings of the dissentient shareholders. He concluded by moving :—

"*That the liquidators of the Company be and they are hereby authorised to consent to the registration of a new company to be named the Maxim-Weston Electric Company (Limited), with a Memorandum and Articles of Association which have already been prepared with the privity and approval of the Directors of this Company.*"

Mr. J. M. KLENCK seconded the resolution.

The CHAIRMAN, in reply to Mr. Henderson, said that he mentioned at the last meeting that the liabilities of the old Company amounted to between £2,000 and £2,500, and that their book debts, which they looked upon as good debts, were equal to those liabilities, so that they had their patents and plant unencumbered.

A SHAREHOLDER said he would like to know what the Directors were prepared to offer the dissentient shareholders for their holdings, and whether, if there was to be an arbitration as to the value of their shares, it was to be at the cost of the Company.

Mr. ABRAHAMS said he was instructed by the holders of 30,000 shares to intimate their probable dissent from the resolutions before the meeting, and said that they would not be contented with less than 2s. per share, which he thought the arbitrator would award. He had carefully read the agreement, and in all respects he thought it was a very fair one ; but he thought that the 10th clause, which provided for the discretionary retention of the property of the Company by the liquidators until the claims of the dissentient shareholders had been satisfied, ought to be made compulsory.

The CHAIRMAN, in reply to Mr. Abrahams and Mr. Henderson, said that it was provided by the said agreement that the interests of the dissentient shareholders would be submitted to arbitrators, who would determine the value of their shares. In the event of the arbitrators disagreeing an umpire would be called in. With all due deference to the opinion of Mr. Abrahams, he did not think that either the arbitrators or the umpire would estimate the value of the shares of the dissentients at 2s. The liquidators were, however, bound to pay what the arbitrators fixed as the market value of the shares, but he would point out that, under the provisions of the agreement, if shareholders holding more than 30,000 shares should dissent, it would be optional for the new Company to decline to carry out the agreement, and in that case there would be no alternative but to wind up.

Mr. J. M. KLENCK said that the scheme now proposed was in the interests of all the shareholders, who, he hoped, would give their sanction to the carrying of it into effect.

Mr. NEWTON emphasised the fact that the dissentients were only entitled to the value of their shares as determined by arbitration, by the result of which they were bound to abide.

The resolution was carried with six dissentients.

The CHAIRMAN then moved the last resolution as follows :—

"*That the draft agreement submitted to this meeting, and expressed to be made between this Company and its liquidators of the one part, and the Maxim-Weston Electric Company (Limited), of the other part, be and the same is hereby approved, and that the said liquidators be and they are hereby authorised, pursuant to Section 161 of the Companies Act, 1862, to enter into an agreement with such new company (when incorporated) in the terms of the said draft, and to carry the same into effect with such, if any, modifications as they think expedient.*"

Mr. HILDYARD seconded the resolution, which was agreed to with six dissentients.

On the motion of Mr. NEWTON, a vote of thanks was passed to the Chairman, which terminated the proceedings.

Charles L. Baker and Co. (Limited).

The second ordinary general meeting of this Company was held at the registered office, Booth-street, Manchester, on Tuesday last, December 21st, 1888, Mr. J. E. Longson in the chair.

Mr. GEORGE W. LOWCOCK (the Secretary) having read the notice convening the meeting, the report and accounts were taken as read.

The CHAIRMAN said that the Directors had much pleasure in meeting the shareholders and laying before them the accounts of the first year's working. This they considered very satisfactory, considering the business had been in the hands of the company so short a period. They had pleasure is recommending a dividend at the rate of 10 per cent. per annum on the Ordinary shares and 5 per cent. on the Deferred shares. The business of the Company had largely increased, and they were sure that the shareholders would be gratified to learn that they had secured several valuable contracts, which would keep the works fully occupied for some length of time.

Messrs. Trevor and Pilling were re-elected auditors, and a vote of thanks to the Chairman concluded the meeting.

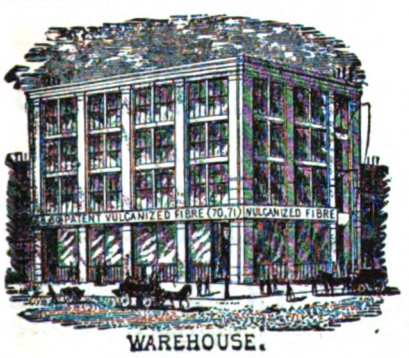
CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended December 21st, 1888, amounted to £6,270.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended December 21st, 1888 (after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company), were £5,268.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The traffic receipts for the half-month ended December 15th, 1888, were £2,790, as compared with £2,807 in the corresponding period of 1887.

THE NON-CONDUCTOR OF ELECTRICITY.



WAREHOUSE.

VULCANISED FIBRE,
PATENTED.

This new material is supplied in two qualities, Flexible and Hard.
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.
It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.
The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.
Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 555.—Vol. XXII. FRIDAY, JANUARY 4, 1889. Price 4d.

NOTES.

It needs hardly to be said that the inaugural address which will be delivered on Thursday evening next by Sir William Thomson, as President of the Institution of Electrical Engineers, is awaited with keen expectation throughout the scientific world as an event of the very first importance. Whatever Sir William may have to say, whether on the physical aspects of those recondite mathematical studies which he has made peculiarly his own, or on the practical applications of scientific knowledge, will be followed with the same degree of attention. We think that it will be found that a large portion of Sir William's address will be devoted to a consideration of the probable and the ascertained relations betwixt ether, electricity, and ponderable matter. Questions relating to the propagation of electro-magnetic and electro-static induction, to which the researches of Hertz and the discussions at the recent meeting of the British Association have lent renewed interest, will probably be touched upon. The conditions of stability of molecular rotations and their connection with magnetic and electro-magnetic phenomena will be illustrated by reference to experiments with the gyrostat. But whilst we may confidently anticipate that Sir William's address will throw new light upon these dark places, yet we believe it will be found that he feels himself driven to the conclusion that any wholly satisfactory and comprehensive theory is beyond our present powers of imagination.

Speaking of Sir William Thomson one thinks naturally of the mariner's compass, and this reminds us of a singular rumour of which we have recently heard, to the effect that the use of the compass is about to be altogether superseded. A method is said to have been discovered by which the true North may at any moment be ascertained by means of a device which is wholly independent of magnetic action. The reading is, however, obtained by electrical means, and it is said that a well-known Berlin firm of electricians has secured the patents. Our informant also surmises that gyroscopic action is involved. We mention the story for what it may be worth.

Some misapprehension appears to exist as to the motives for the action which the Board of Trade has taken in reference to the applications for licenses for the supply of electricity within the Metropolitan area. We therefore publish in another column the text of the memorandum, and it will be seen that the Board is merely anxious to escape the responsibility which the issue of a license would devolve upon it. On the whole, we think that this action is to be regretted. It is within the power of the Board of Trade to create licenses for any lesser number of years than seven, and if they would issue licenses for terms of one, two, or three years, by the time these had expired the question would be ripe for Parliamentary decision on the basis of an order extending for the full term of forty-two years. Probably one reason which has induced the Board to take this step is the difficulty which it still experiences in determining whether or not more than one license or order is to be granted for any given area. As matters stand the ultimate decision as to the fate of the huge schemes now in progress will be in the hands of a Parliamentary Committee, who will have the advantage of hearing arguments for and against the proposals, but who will not be in possession of material evidence upon their practical working such as a somewhat bolder policy on the part of the Board of Trade might have provided them with.

Mr. Beeston, of the House-to-House Electric Lighting Company, casting about for the most dignified means of communicating his private opinion upon the Deptford scheme, happily bethought him of being "interviewed" by a reporter of a financial paper. Mr. Beeston is well assured that both technically and commercially the London Electric Supply Corporation is altogether on the wrong road. Well, time will show; for our own part we do not care to prophecy until we know a good deal more than anybody—except, apparently, Mr. Beeston—does at present. We quite agree with him, however, in the belief that "there is no big monopoly in store in electric lighting." We also recognise the fact that the House-to-House, in common with other companies who are working on well ascertained lines, are fully entitled to claim public confidence on the ground that their proposals are not of an experimental character.

In *Wiedemann's Annalen*, Herr R. Von Helmholtz describes a pretty and singular experiment. A jet of steam escaping from a hole one or two millimetres in diameter is lighted obliquely and observed upon a dark background. The jet is then invisible at the base and whitish at the top. But if a pointed wire connected with a static induction machine be brought near, the jet immediately assumes a brilliant tint, whose colour depends upon the potential of the point. The same effect is produced without the aid of electricity by merely

Digitized by Google

holding a heated body near the jet. The phenomena is due no doubt to a modification of the size of the particles of aqueous vapour, and in the hands of Prof. HELMHOLTZ we may expect the experiment to throw new light on some of the most difficult problems of molecular physics.

SINCE writing the above Mr. A. E. MAYOR, who at one time held the appointment of Chief Electrician in the Chilian Navy, has informed us that he has frequently observed the effect described when a beam of electric light has been thrown upon a cloud of steam. For naval purposes this plan of blowing off steam and projecting the beam upon the cloud forms a most efficient method of signalling, and in action it is much better than any device involving the suspension of lamps from the yard-arm, since it does not reveal the exact position of the ship to the enemy. The latter method, however, is in vogue in the French, Spanish, and American navies, and recently Commandant ARDOIS, of the Spanish service, has devised an improvement on the Conz system, which latter was described in *The Electrician*, August 3rd, 1888, p. 401. The Ardois system enables any one of sixty-two different combinations of five red and five white lamps to be effected by a single movement of the commutator. A full description of the device will be found in the *Révue Industrielle* of the 22nd ult.

AN engineering contemporary mentioned last week that Messrs. GOOLDEN AND CO. "have proposed to connect the search lights of war vessels with the sights of the quick-firing guns in such a way that when the light is bearing on an object the gun is also. In this way they expect to save time when every minute is of importance, as it is during the approach of a hostile torpedo boat." This application of the search light is, however, of even greater importance in the case of heavy guns and long ranges than in the case of short range, quick-firing guns; but it is also attended with much greater difficulty. The straight line of light does not in this case coincide with the trajectory of the shot, and when it is also recollected that the gun is fired from a rolling platform, it is evident that before the method can be of any use some means must be provided for applying a correction suited to the range, and this correction must also be well-nigh instantaneous. We happen to know that this question has for some time occupied the attention of our own engineers. In the Chilian navy, however, Mr. MAYOR some time ago achieved remarkable success with this method of firing, and we believe that he had also an electrical device which ensured firing on an even keel. We hope shortly to publish some further information on these points.

WE learn with considerable satisfaction that the Patent Office is about to resume the publication of the excellent series of classified abridgments of specifications, the preparation of which has been practically suspended for some years. The arrears of the work are, however, enormous, and a large staff of special abridgers is now being organised, in the hope of eventually bringing the undertaking down to date. The electrical patents are divided into six sections, and unfortunately not one of them is brought to a later date than 1876, so that they stop short exactly at the point where the modern developments may be said to have commenced. We do not know whether the Patent Office has yet completed the selection of its staff, but considering the importance and the difficulty of the task before it, we trust that steps have been taken to secure thoroughly competent men for the work. It may not be out of place if we add that approved applicants are permitted to take the work away with them to be done at their own convenience, the payment being at the rate of 5s. for each specification, irrespective of its length.

THE abridgments of electrical specifications from 1766 to 1876 (which may be obtained at a total cost of only 13s. 8d.) are classified in six divisions, as follows:—I. Generation of Electricity and Magnetism; II. Conducting and Insulating; III. Transmitting and Receiving Signals; Controlling Mechanical Action and Exhibiting Electric Effects; IV. Electric Lighting, Igniting, and Heating; V. Electro-Deposition and Electrolysis; VI. Electric Motive Power Engines and similar apparatus. This classification may have been very suitable up to 1876, but we sincerely hope that the Patent Office will recognise the fact that it is no longer capable of meeting the requirements of the case. A very different and much more detailed classification is, indeed, absolutely necessary for the efficient carrying out of the scheme; and this is a point to which the compilers should give the fullest consideration.

THE Bill for Technical Industrial Education which has been introduced in the local Kensington Parliament by Prof. PERRY, and to which we have given all the publicity our pages will afford, is to be commended at all events for the directness and simplicity of its provisions. Shorn of formalities, the Bill enacts that School Boards shall provide technical schools; that boys and girls employed in workshops shall attend these schools; and that the employers shall pay the fees. These are rather startling propositions, and anywhere else but at Kensington they would probably have a warmer reception than the promoters seem to bargain for. A Kensington Parliament, however, ought to be composed of educated and intelligent men; and we doubt not that Prof. PERRY'S Bill will receive that criticism which in his letter to us he frankly invites. If any of our correspondents conversant with the needs of industrial life also care to respond to that invitation through our columns, we shall be pleased to hear from them.

Our influential and important contemporary the *Municipal Review* came out the other day with some very unkind remarks on what it is pleased to call "Electric Lighting Botchers." That there have been botchers, and more unhappily still, that there *are* botchers, in electric lighting (as well as in journalism and a few other professions) cannot be denied. But the *Municipal Review* says that all promoters of electric lighting, at least in London, are "a sorry lot." And what "is surprising," our contemporary proceeds, "to people who are accustomed to think for themselves is the want of ingenuity and

Digitized by Google

originality displayed." Everyone is, of course, aware that the intellectual development of the average electrical engineer is of a singularly low order, otherwise he would not have to come to the *Municipal Review* to be taught his business. Central lighting stations constructed according to the methods now in vogue, according to the same authority, "can readily ruin any neighbourhood"; and what ought to be done is to give up the use of steam and resort exclusively to artesian wells as a source of motive power. This is a grand idea; and as for some trifling practical difficulties which suggest themselves to the benighted electrician, doubtless our contemporary knows exactly how to overcome them. Hitherto it has been thought that artesian wells are only attainable under certain special geological conditions; but this is perhaps a mistake. (By the way, the well at La Chapelle, in Paris, which is now used as a source of motive power for electric lighting, took only 24 years to dig.) Finally, our contemporary says that it is a disgrace to our "bosted" (*sic*) civilisation that the lighting of London by electricity should be left to chance, and thinks that "no time should be lost in establishing a central authority composed of men acquainted with the subject and the wants of the people of to-day." Would it not be better still to entrust the whole business to the editor of the *Municipal Review*?

We would call special attention to the announcement that Prof. Perry proposes to give a working knowledge of the Differential Calculus in a special course of twelve lectures and exercise work to electrical and mechanical engineers. It is to be hoped that this opportunity will be welcomed by a large number of those who have only an elementary knowledge of algebra and trigonometry. Men of this class usually grow disgusted when they see a sign of integration or differentiation, and yet they are continually using the ideas of the Calculus without knowing it. The first lecture will be given at the Finsbury Technical College on the 15th of January, at 7 p.m.

The *Gas World* "thinks that whenever an electric company applies for powers to supply a certain area their claims should be resisted by some recognised organisation." Poor *Gas World*!

Bedford.—The Town Council of Bedford has granted £25 to a committee of inquiry as to electric lighting.

Restoration of Telegraphic Communication with British Guiana.—We are informed that the cable between Trinidad and Demerara is now opened.

Proposed Electric Lighting at Bishop Stortford.—A proposal is on foot in this town to form a local company for electric lighting purposes, with a capital of £10,000 in £5 shares.

Election Intelligence.—Sir John Pender, K.C.M.G., Chairman of the Eastern Telegraph Company, is the Unionist candidate for the Govan Division of Lanarkshire, in the vacancy created by the death of Sir W. Pearce.

The Electric Light on Torpedo Boats.—The Austrian naval authorities are using Parsons's turbo-electric generators on board their torpedo boats. The dynamo runs at 10,000 revolutions a minute, and develops 28,000 watts.

Calendars for 1889.—We have received some artistic and useful calendars for the New Year from the Anglo-American Brush Corporation, the Commercial Cable Company, and the Direct United States Cable Company.

Barnet.—At a meeting of the Barnet Local Board, held on Tuesday evening last, the resolutions antagonistic to Mr. Joel, which had been passed at the previous meeting were rescinded, and a cheque for the last quarter's lighting was handed to Mr. Joel.

Folkestone.—It will be seen in our advertisement columns that the Electric Lighting Committee of the Corporation of Folkestone have been authorised to enter into a provisional contract for lighting a part of the town with arc lights. Tenders must be sent in by the 23rd inst.

The Telephone at the Paris Exhibition.—The Société Générale des Telephones will place exhibitors at the forthcoming International Exhibition in telephonic communication with their Paris system, at a charge of 300fr. The service will commence on 1st May and continue to the close of the Exhibition.

Dundee.—Messrs. Gilroy, millspinners, of Dundee, have laid an underground cable between their calender and their jute sheds, a distance of 200 yards. The current generated by the dynamo at the calender is used to drive a motor at the jute sheds, which works the lifts and other machinery. The current is also used for lighting purposes.

Academie des Sciences.—The prize which the Académie des Sciences has offered without result for several years in succession for some important advance in the theory of the electrical transmission of power has this year been withdrawn on the suggestion of MM. Deprez, Bertrand, Mascart, Becquerel, and Maurice Levy, who formed the committee of award.

"Electricity at Work."—An interesting lecture under the above title was recently delivered at Georgetown, British Guiana, by Mr. S. Vyle, Government Electrician. A large audience, including the Governor, was present. During the lecture telegraphic messages were sent and received from New Amsterdam and Trinidad, and the electric light was shown and explained.

Portsmouth Dockyard.—The *United Service Gazette* says that plans are being prepared for the erection of an electric lighting station near the present electric lighting shop at Portsmouth Dockyard which will transmit electricity for lighting purposes to the ships fitting in the repairing basin, and also to the new battle ship which is to be built in No. 13 dock during the next financial year.

The Telegraph in the South African Gold Fields.—The activity in the mining shares of the Witwatersrand Gold Fields has recently increased to such an extent that the telegraph office at Johannesburg has been overwhelmed by the number of messages between that centre and other South African markets and with London. A foreign mining journal says that as an average the number of despatches is 1,000 daily, and the daily receipts have been as much as £200.

City and Guilds of London Institute Old Students' Association.—The question of the further issue of a *Journal* has been under consideration of the committee for some time past, and it was finally resolved at the meeting of Dec. 18th to bring out jointly with the Central Institution and the Technical College, Finsbury, a *Journal* to represent these colleges and the Old Students' Association. A circular and subscription forms will shortly be posted to members, and it is hoped that all will become subscribers.

Telegraph Development in the River Plate.—The following table, showing the growth of the telegraph receipts of the River Plate for the ten years ended December 31, 1887, is taken from the official report:—

Year.	Revenue.	Year.	Revenue.
1878	$81,000	1883	$223,000
1879	95,000	1884	167,000
1880	114,000	1885	244,000
1881	118,000	1886	248,000
1882	221,000	1887	407,000

Electricity at Horsington.—At an Art, Scientific and Industrial Exhibition recently held at Horsington, an interesting display of the varied uses to which the electric current can be put was made under the superintendence of the Rev. J. D. C. Wickham, rector of the parish. A battery of accumulator cells was carted from the rectory to the school room where the exhibition took place, and supplied a large number of lamps to light the rooms

Digitized by Google

and approaches, besides driving motors. The cells were charged by a dynamo lent by the rector, and the electrical portion of the exhibition attracted the greatest attention and interest.

Society of Arts.—The following arrangements have been made for the Wednesday evening meetings of the Society of Arts after Christmas:—On the 23rd a Paper will be read by Prof. George Forbes, on "Electric Meters for Central Stations." Papers for which dates have not yet been fixed will also be read on the "Manufacture of Aluminium," by Mr. William Anderson; on "Secondary Batteries," by Mr. Preece; on "Automatic Selling Machines," by Mr. J. G. Lorrain; on "Arc Lamps and their Mechanism," by Prof. Silvanus Thompson; and on the "Use of Spirit as an Agent in Prime Movers," by Mr. A. F. Yarrow.

The Proposed Underground Electric Railway.—Mr. Gainsford Bruce, Q.C., M.P., presided on Wednesday at a meeting of the ratepayers of Holborn, in opposition to the proposed line of underground electric railway between Piccadilly and Holborn-circus. Mr. L. Isaacs, M.P., described the railway as one which commenced nowhere and which ended nowhere. Mr. R. R. Hazard, one of the directors of the company, denied that the line would interfere with the sewers or the gas or the water. A resolution was passed in opposition to the scheme, and a committee was formed in order to take steps for opposing the London Central Subway Railway Bill in Parliament.

The "Brockie-Pell" Arc Lamp.—We learn that after using forty of these lamps for about three years at the Royal Laboratory, Woolwich, the Government have given an order to Messrs. Johnson and Phillips for twenty more to light the new saw mill at the Arsenal. The same firm have also recently shipped a large number to Australia for the purpose of lighting nearly three miles of streets in one of the principal towns in New South Wales. The "Brockie-Pell" lamp being now so well and favourably known, we are not surprised to hear that the demand generally this winter has been so great that Messrs. Johnson and Phillips, who are the sole makers and licensees, have had to considerably extend their workshops in this department

The Institution of Civil Engineers.—The following table shows the progress of this society (incorporated by Royal Charter) during the last decade and the past twelve months, the date given, the 2nd of January, being that of the establishment of the institution in the year 1818:—

January 2nd.	1889.	1888.	1879.
Members	1638	1596	1081
Associates	3003	2855	1717
Honorary Members	18	20	16
Students	957	947	535
Totals	5616	5418	3349

Long Life in an Incandescent Lamp.—The Bigelow Carpet Company, of Clinton, Mass., U.S.A., have been operating a Brush incandescent electric light plant since 1885. Some of their Swan incandescent lamps have made wonderful records in the length of their burning hours. They have recently forwarded a lamp to the parent company in Cleveland, which they commenced using on January 25th, 1886, since which time it has burnt 7,400 hours, having been in use in the dynamo room, and has not been turned off over half a dozen times since it was placed in position. It has been left in circuit, and been always lighted whenever the dynamo was running. The lamp is not as yet burnt out, nor blackened in any way. It is still burning in the Brush offices in Cleveland.

New Catalogues.—We have just received a copy of Messrs. Woodhouse and Rawson's new catalogue, which seems as replete as ever with illustrations and descriptions of every sort of electrical fitting. Amongst other things we notice a large variety of the well-known Woodhouse and Rawson incandescent lamps, and some very artistic illustrations of electric brackets, standards, and electroliers.—The Edison and Swan United Electric Light Company have also just issued a new price list, containing a good deal of information about the numerous lamps and lamp accessories which the company supplies. We have also lately received the new illustrated catalogue of the United Asbestos Company, which makes a speciality of Italian as well as Canadian asbestos. The prices seem to compare very favourably with those of other manufacturers.

The Lighting of the City.—At the various Wardmotes held in the City on Friday, the 21st ult., a few references were made to the lighting of the streets by electricity. At the Aldgate Wardmote the following resolution was passed:—"That this Wardmote is of opinion that the time has arrived when the City should be illuminated by the electric light, and regrets the slow progress heretofore made in accomplishing this. They therefore hope the members of the ward who are members of the Commission of Sewers will exert themselves to obtain the carrying of it out, and as quickly as possible." At the meeting of the Bread Street Ward Mr. Alliston, one of the representatives re-elected to the Court of Common Council, said he thought the lighting of the City by electricity, and the abatement of the smoke nuisance, should receive consideration.

Electricity in our Homes and Workshops.—A popular lecture, entitled "Electricity in our Homes and Workshops," was recently delivered at Norwich by Mr. Paris, of the firm of Laurence, Paris and Scott. The lecture was of a most interesting nature, and was largely illustrated by practical experiments. Mr. Paris laid great stress not only upon the beauty and manifold advantages of the electric light, but upon its harmlessness. The lecturer stated it as his opinion that there was a great future before electricity as a motive power, and that he looked forward with confidence to the day when many industries which are now carried on in huge factories would employ people, as of old, in their own homes. A hearty vote of thanks was accorded to Mr. Paris, who, in acknowledging it, repudiated the idea that electricity was in its infancy; it was no longer an infant, but a vigorous youth.

Progress in New Zealand.—The *New Zealand Herald* says that Mr. Horton, the newly-appointed electrician of the Reefton Electric Light Company, "recommends the substitution of Swan-Edison incandescent lamps for those of Thomson-Houston manufacture, at present in use by the company. He says the lamps are altogether unsuited to dynamo. (!) He further recommends the use of overhead wires in place of an underground cable, and if these changes are effected he assures the directors there is not the slightest doubt in the world of the complete success of the installation. He is well pleased with the design and condition of the plant otherwise, and has expressed the opinion that the dynamo has a full capacity for 500 lamps. The company have sent to Melbourne for the required new plant, which will be shipped as quickly as possible. Confidence is again re-established in the venture."

Mr. Gisborne on Telegraphy and Telephony.—Mr. F. N. Gisborne recently gave an interesting lecture before a large audience at the McGill University, Montreal. Mr. Gisborne informed his hearers that his desire was not to entertain those present, but to so clearly explain the first principles of telegraphy, telephony, the localisation of breaks in ocean cables, and lightning, that every person present might leave the hall with a satisfactory knowledge of the basis of modern electrical apparatus and inventions. By aid of large diagrams the various telegraph instruments, the Bell telephone, and the dynamo were explained in such simple and non-technical language as to call forth repeated applause from all present. Mr. Gisborne also referred to the endeavours which had been made in the past to establish direct cable connection between England and Canada *viâ* the Straits of Bell Isle. Another attempt was about to be made, and Mr. Gisborne believed the Dominion Government would regard such a movement with favour. The lecture was received with great applause.

Edinburgh Association of Science and Art.—A meeting of this Association was held recently, at which Major-General Sir R. Murdoch Smith delivered a lecture on Telegraphic Communication with India. He gave a general account of the efforts which had been made subsequent to the outbreak of the Indian Mutiny to establish telegraphic communication with the country, and the difficulties that had to be overcome before success was achieved. Of all the great inter-continental telegraphs it was by far the greatest importance to the general in-

Digitized by Google

terests of the empire. This would be the case even if India alone were concerned, but its importance was greatly enhanced by the fact that upon that system depended our telegraphic communication with the Australian Colonies, Burmah, the Straits Settlements, the East Indian Archipelago, China and Japan. It was the first system of the kind successfully established, and one reason for his dealing with the matter was that from its first beginning, about twenty-five years ago, until quite recently, he happened to be perfectly familiar with its history.

The Telephone and the Fire Brigade. — The National Telephone Company have received from the Watch Committee of the Birmingham Corporation a well deserved recognition of the usefulness of the telephone to the police and fire brigade departments. The committee's letter says:—"Not only are subscribers able to convey information of the outbreak of fire on their own premises, but on several occasions fires occurring in the neighbourhood of a telephone subscriber's office have been reported to the Central Station, and the delay which might otherwise have occurred, and which is so disastrous, has been avoided. The sub-committee consider this not the least of the many advantages which your system offers, and in proportion with the extension of the system will the benefits referred to be increased." It may be added that recently an outbreak of fire took place at the Britannia Railway Carriage and Waggon Works, a distance of one and a-quarter miles from the Central Fire Station. The men in charge telephoned to the fire station at once, and in nine minutes from the despatch of the message the steam fire engine arrived at the scene of the outbreak.

New Street Fire Alarm.—Mr. George Durham, of Stockport, has just completed a service of street fire alarms, of his own design, for the Stockport Corporation. The apparatus combines electric and telephonic communication with the police station, and the alarm is given automatically. Like other instruments of its kind it is contained in an iron box. In the lower part of the door is a small pane of glass, against which a button presses from the inside. To make use of the instrument it is necessary to break the glass; this at once releases the button, and completes the circuit. A simple arrangement of dials enables the person at the police office to tell from which alarm box the signal comes. A special feature of this apparatus is the variety of ways in which it is possible to complete the circuit should the button by any chance fail to do so. The telephonic apparatus is available as soon as the door of the box is opened. There are twelve of these alarms in Stockport, which have so far worked to the satisfaction of the Corporation, signals being sent and answers received in from three to six minutes. Should the machines continue to act satisfactorily they will probably be increased in number.

Central Station Lighting at Derby.—The following tariff of charges per annum which Messrs. John Davis and Son propose to adopt at their Derby central station, referred to in *The Electrician* of December 21st, may prove of interest:—

INCANDESCENT LAMPS.

Nominal C.P.	Dusk till 8 p.m.	Dusk till 9 p.m.
	£ s. d.	£ s. d.
10	1 5 0	1 15 0
20	2 0 0	2 15 0
32	3 10 0	5 0 0
150	8 10 0	11 10 0
200	10 10 0	14 10 0
300	12 10 0	16 0 0
500	20 0 0	30 0 0
ARC LAMPS.		
. 400—500	14 14 0	18 18 0
1,000	18 0 0	24 0 0
1,500	25 0 0	35 0 0

The Telephone at the Stock Exchange.—The first day's experience of the use of the telephone in the Stock Exchange (says the *Financial News*) has been very successful. The introduction of this important means of facilitating business has been brought about under the auspices of the Exchange Telegraph Company; but the system is actually worked by the United Telephone Company, who are entitled to whatever credit arises out of the working. It will require some little time before the system can work with the perfection which is required; but the arrangements made are very satisfactory and sensible. A portion of the cloak room at the foreign door of the "House" has been devoted to the telephone service, and there 12 sound-proof boxes have been erected. The *modus operandi* is this: When a member desires to speak from his office to anyone in the "House," he calls up the Stock Exchange and mentions whom he wishes to speak to. A waiter has been put in charge of the telephone room, and he has speaking tubes to all the different doors of the "House" where members are called. When anyone is called for over the telephone this waiter speaks to the waiter at the proper door, who summons the member in the usual way, with the addition of a sign which is to be recognised to mean "telephone." The member or clerk then goes to the call office, is told the number of the person desiring to speak with him, and that is all. The process appears to be cumbrous, but it is necessary, and it works very well.

The International Congress of Electricians, 1889.—The organising committee of the International Congress of Electricians met at Paris on Dec. 17th and settled several important matters, amongst others the rules and regulations relating to the forthcoming gathering. The following are some of the most noteworthy points:—Article 2. The Congress to last eight days. Article 3. All persons will be considered members of the Congress who have given in their names to the president of the organising committee before the opening of the meeting, or who put their names down during the session, and who have paid their minimum subscription of 20 francs. Article 5. At its first meeting the Congress will immediately proceed to form its bureau. Article 6. The bureau of the Congress will arrange the distribution of the work of the meeting, will fix the programme for each day, will direct the discussions, and edit the reports. Article 7. Members of the Congress alone will have the right to take part in the sittings, to present Papers, and to join in the discussions. Article 10. The reports will be printed and distributed among the members of the Congress. Article 11. A detailed report of the work of the Congress will be published under the direction of the bureau, and each member of the Congress will have the right to a copy of this report.—The organising committee also definitely decided on its programme (see *Electrician*, December 14th). All communications relating to the Congress should be addressed to M. Mascart, president of the organising committee, 176, Rue de l'Université, Paris.

The Projected Electric Lighting of Cowpen.—About 120 owners of property and ratepayers resident in Cowpen have signed a petition against the adoption of the electric light in the township, and it has been forwarded to the Board of Trade. The petitioners say that they are informed that the Cowpen Local Board have entered into an arrangement with Messrs. Nicholson and Jennings, electrical engineers, of London, to light the district, or some portion of it, with the electric light, notwithstanding that it has hitherto been efficiently lighted with gas, and that all the gas lighting plant is fixed in the streets ready for use. They believe the electric light to be quite unnecessary, and that it will be exceedingly costly in comparison with gas lighting. They also understand that it is the intention of the Board and Messrs. Nicholson and Jennings to proceed immediately with the electric lighting, and not to seek any license or Provisional Order from the Board of Trade until after some system of electric lighting has been installed. Understanding that electric lighting can only be adopted after statutory powers have been obtained from the Board of Trade, the petitioners pray the Board to intervene by initiative in this matter, and order further proceedings to be stopped until the Board shall have held a public inquiry into the matter. At the last meeting of the Cowpen Local Board a petition in opposition to electric lighting was presented from the Blyth Property Owners' Association, in which they pointed to the danger of the town remaining in darkness, and also to the fact that in other towns electricity had been tried and abandoned, and furthermore that gas was cheaper.

NOTES ON ELECTRO-MAGNETIC INDUCTION.

BY DR. J. A. FLEMING, M.A.

(Continued from page 216.)

By the help of the same apparatus Blaserna investigated the rise of a current in a coil when the same is placed suddenly in connection with a constant source of electromotive force. For the "make" extra current only one of the revolving interrupters was used, and the circuit was completed by this means of a battery, galvanometer, and coil. When the commutator was revolved it first started the current and then after an interval cut it off again, and the effect on the galvanometer is due to the sum of all these small quantities of electricity so cut off and integrated whilst the current is in process of increasing. As the duration of the time of contact was increased the galvanometer deflection increased (speed of revolution remaining constant), but when the time of contact was long enough to fully establish the current, then increase of speed of rotation did not increase the galvanometer deflection. By this apparatus the fact was established that the primary current established itself in its coil by a series of oscillations.

Similarly, on breaking the circuit the course of the current was investigated. For this purpose one revolving interrupter, I, was inserted in the circuit of a battery, B, and coil C, and from the ends of the coil (*see* Fig. 17) other wires were brought and led through the galvanometer G, and other interrupter I', arranged as a shunt on the coil. The break in the battery circuit at p was so arranged that each time the current was fully established before being broken again. The break in the galvanometer or shunt circuit was so arranged relatively to the other that the shunt circuit was closed a little before the

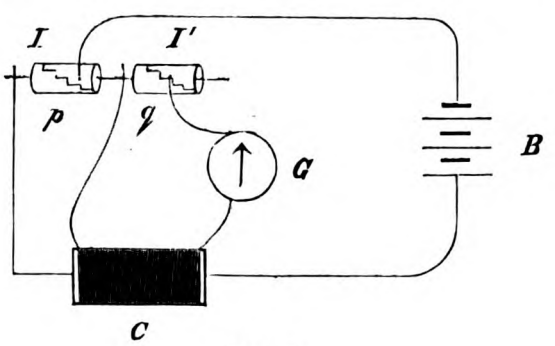

FIG. 17.

battery circuit was broken, and then opened at a definite interval afterwards. In this way there was a little flow of current through the galvanometer due to the steady current, but this could be estimated and allowed for. On plotting out a current curve from the quantity curve it was found that the current decayed away on interrupting the circuit by a series of oscillations which followed each other much quicker than those on the establishment of it, and the whole duration of the extra current at "break," or the time of falling from steady current to practical zero was less than the time required to fully establish the current. It was found that the first oscillation, on beginning to interrupt the steady current, had a much greater amplitude than any of those on starting the current.

The duration of an oscillation was perhaps three or four ten-thousandths of a second, and about 50 to 100 oscillations probably happened before the current became steady; hence the whole duration of the variable period, or of the extra current, was about two to three-hundredths of a second. Very roughly, the nature of the oscillatory character of the current at the make and break might graphically be represented by the diagram in Fig. 18.*

Blaserna drew from his observations the deduction that there is an interval of delay in the starting of the secondary currents, and that a small but measurable time elapses between the instant of making and breaking the primary circuit and the beginning of the secondary current. From this he made a calculation as to the velocity of electromagnetic induction, and he also stated that the interposition of dielectric substances such as glass or shellac between the coils reduced the so calculated velocity.

Bernstein (Pogg. *Ann.*, Bd. CXLII., p. 72, 1871) repeated these observations of Blaserna, but did not confirm these last results. He found that the first oscillation always began at the instant of breaking or making the primary circuit, and he found no effect produced by the interposition of dielectric media.

Helmholtz has carefully examined these results of Blaserna and criticised them.* He remarks that Blaserna used for his coils flat spirals of wire with many turns, and also he used the current from several Bunsen cells to create the primary current. Not only do the spirals act like a condenser, giving the whole apparatus a sensible electrostatic capacity, but the use of a battery of high electromotive force causes a considerable spark at the break, which spark has a very sensible and rather irregular duration. Also in Blaserna's experiments, the two circuits were placed at various distances apart. If a current is started in a primary coil the effect of the induced current created in the secondary by its re-action on the primary is to hasten the rise of the primary current, and at the break to accelerate its decay. As the secondary circuit is moved further off this effect is less marked. Hence, the rise and fall of the primary is more gradual and the arrival of the secondary cur-

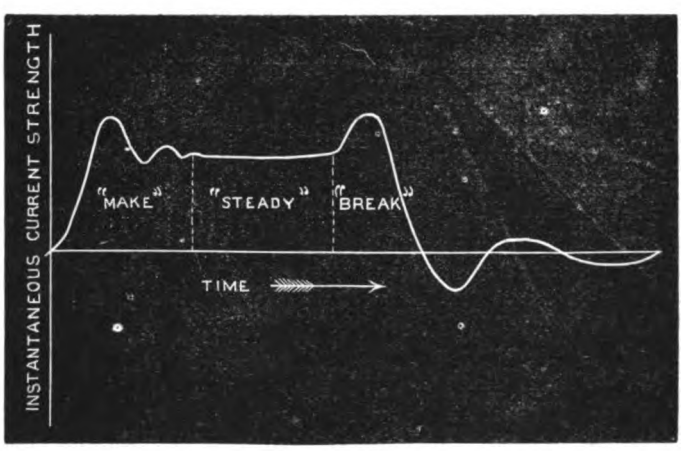

FIG. 18.

rent at its maximum value is more delayed. From this results, then, an apparent retardation of the time of the arrival of the maximum of the induced current.

Helmholtz conducted a series of experiments by means of his pendulum chronoscope. A heavy iron pendulum, P (*see* Fig. 19), the lower end of which carried two plates of agate, could be made to execute one swing and then be caught by a detent. These plates of agate in the course of the swing were caused to strike against and tip over two little levers l, l'. One of these levers was fixed, and the other could be moved forward so as to make the blows successive. One was made to break the circuit of a primary coil, *Pr*, when tipped over, and the other by its movement separated a connection between a condenser and the ends of a secondary coil, *Sec*, attached to it.

These being arranged, the fall of the pendulum executed these two "breaks" successively, and by an interval of time capable of being calculated from the known motion of the pendulum. The two circuits were placed 170 centimetres apart. The primary consisted of 12 turns of thick wire, and the secondary of 560 turns of fine wire. The current was sent from one Daniell cell. The two ends of the secondary were connected to the two plates of the condenser, and when the pendulum fell it broke the primary current and started in the secondary circuit an oscillatory current reverberating to and fro in the secondary wire, the condenser acting as a resonator. At a definite interval

* In *The Electrician* for June 1, 1888, a curve is given by Mr F. Higgins, showing the rise of current in the magnets of type-printing telegraphs, and the oscillatory character of the current at starting is well marked. Mr. Huggins's curve gives the results of actual observations.

* Helmholtz, "On the Velocity of the Propagation of Electrodynamic Effects," *Phil. Mag.* Ser. 4, Vol. XLII., 1871, p. 232.

Digitized by Google

after rupture of the primary the condenser was separated and examined by a Thomson electrometer. The charge in the condenser showed the *phase* of the electrical oscillation existing at the instant of such separation. In one case Helmholtz observed 35 oscillations in $\frac{1}{80}$th of a second. In order to discover if any retardation took place with increased distance of the coil, it was necessary to fix attention upon some phase in the oscillations. The successive zero points of the current were very sharply defined, and suitable for this purpose. Helmholtz found that alteration of the distance between the primary and secondary coils made no perceptible difference in the position of the zero points, and that, as far as the apparatus he was using could detect, the velocity of the electro-magnetic impulse must be greater than 195 miles per second. He pointed out in this paper that the commencement of the secondary current is not a sharply marked thing. The spark which takes place at break of the primary lasts an appreciable time, and all this time the primary is dying gradually, and the induced current therefore is increasing. The period of duration of the break spark may be something like $\frac{1}{15000}$th to $\frac{1}{16000}$th of a second, and is, therefore, a large fraction of the duration of a single electrical oscillation, which amounted to about $\frac{1}{2811}$th of a second. The

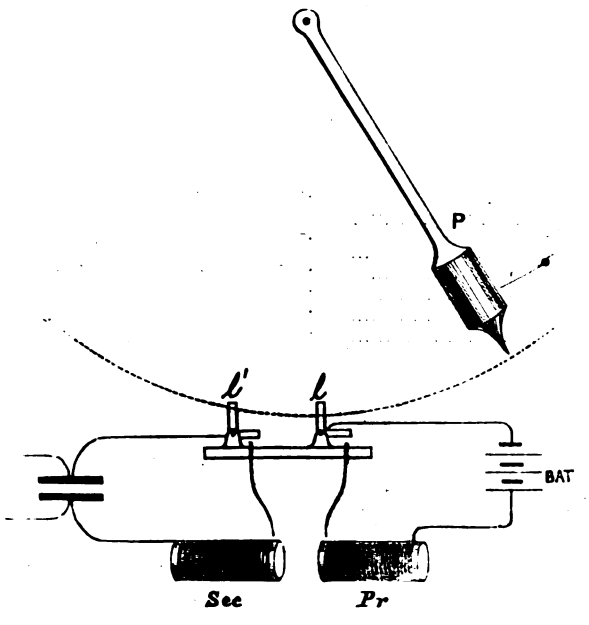

FIG. 19.

duration of the break spark can be found by observation of the time which elapses from beginning of break up to the first zero point of the secondary current oscillations, as compared with the mean value of the duration of an oscillation. The interval up to the first zero point is the duration of the break spark *plus* the time of half a complete oscillation. The duration of the spark is never constant, and depends a good deal on the amount of platinum thrown off from the contacts each time. The average duration of the spark in Helmholtz's experiments was found to be about one-tenth of the whole period of an oscillation. Helmholtz also noticed in some earlier observations evidence of electrical oscillations set up in a flat spiral, one end of which was insulated. In this case some 45 oscillations were detected in the space of $\frac{1}{80}$th of a second. Prof. Henry also noticed that the time of subsidence of the current, when the circuit is broken by means of a surface of mercury, is very small, and probably does not much exceed the ten-thousandth part of a second. It has, however, a quite appreciable duration, for Prof. Henry found that the spark at ending presents the appearance of a band of light of considerable length, when viewed in a mirror revolving at the rate of six hundred revolutions per second.

Bernstein, with the aid of a contact break somewhat different from that used by Blaserna, also examined the duration of the oscillations set up in a secondary coil. He found that the duration of the first oscillation at breaking primary was longer than that of the subsequent ones. The mean duration when using a single Grove cell in the primary circuit was ·0005 second, and when using a Daniell cell only ·0001 second. We shall return later to consider more recent researches on these electrical oscillations.

(To be continued.)

LIGHTNING CONDUCTORS.—VII.

BY DR. OLIVER LODGE.

(Continued from page 189.)

Record of Further Experiments, August, 1888.

41. A circuit was now prepared, of which every detail could be easily determined, and whose self-induction could be varied within certain limits at pleasure. The main part of it consisted of two wires stretched parallel to one another, about four inches apart, being supported at their ends by silk threads and glass pillars. To the ends of these parallel wires, and as prolongations of them, were arranged two very small Leyden jars, such as are supplied with an ordinary Voss machine, clipped in a couple of retort stands standing on a wooden table. From the outer coats of these jars, thus woodenly connected, two short wires led straight to the spark micrometer.

Connection with the machine was effected through wooden sticks, so that the machine and leading wires are quite out of the circuit as far as discharges and oscillations are concerned.

It was proved experimentally that none of the circuit beyond the wooden semi-interruption made the least difference. Nor did it matter whereabouts the wood made connection with the jar circuit. An A spark was provided by the universal discharger, which was placed under the two long wires so as nearly to bridge across the gap. This discharger could be shifted along the whole length of the wires,

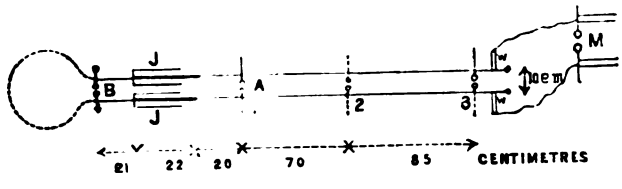

FIG. 9.

J are the two Voss jars arranged as shown in Figure, with long wire continuations, two No. 17 copper wires a decimetre apart. M is the machine and W are wooden connectors. A is the universal discharger, which can be placed in either one of three positions, 1, 2, 3. B is the spark micrometer, with an alternative path completing the circuit shown by a dotted line. Linear dimensions are expressed in centimetres.

and thus the self-induction of the jar circuit varied. Ordinarily three definite positions were employed, one near each end and one near the middle, labelled respectively 1, 2, and 3, as shown in the diagram. The knobs of the discharger and of the spark micrometer are the same as have already been described and experimented on, as recorded in § 21. The dimensions of the whole arrangement are best represented in the diagram.

It is necessary to specify the thickness of the different parts of the circuit:—

Thickness of No. 17 wires	·15	centim.
Thickness of rods inside jars	·98	,,
Thickness of A discharger rods	·60	,,
Thickness of B discharger rods	·58	,,

Capacity and Self-Induction.

The capacity of the two Voss jars in series, and of the two No. 17 wires, amounted altogether to 143 centimetres electrostatic units. This, therefore, is the value of S when the Voss jars are used.

Applying calculation to the rectangular circuit included between the A and the B knobs I make out that its self-induction in electromagnetic measure is as follows:—

For the A knobs in No. 1 position...	$L_1 = 1290$	centimetres.
,, ,, No. 2 ,, ...	$L_2 = 2677$	,,
,, ,, No. 3 ,, ...	$L_3 = 4397$	,,

Digitized by Google

Alternative Paths.

42. A number of alternative paths were now prepared, all consisting of the same length of wire, namely, 235 centimetres, carefully bent into a circle about 2ft. 6in. in diameter, with ends arranged so as to be easily connected direct to the rods of the spark micrometer. They were all the same *length*, but of very different thickness and material, the finer wires being supported upon a hoop of cardboard.

The following table shows their thickness, their ordinarily measured resistance, and their calculated self-induction, for cases where the current keeps to their outer surface :—

Description of wire.	Thickness.	Resistance.	Self-induction L_0.
	Centimetre.	Ohm.	Centimetres.
No. 5 copper	·535	·0048	2,340
No. 2 iron	·71	·0166	2,230
No. 2½ brass	·68	·0051	2,240
No. 18 iron	·11	·254	3,100
No. 18 copper	·12	·092	3,060
No. 24 brass	·05	·89	3,470
No. 25 iron	·045	2·03	3,520
No. 23 copper	·065	·29	3,340
No. 40 copper	·01	2·60	4,230
"Longer leads"	·15	1·95	100,000

Sometimes much longer leads were used, consisting of a pair of No. 17 copper wires, each 38·2 metres long, arranged along and across the room, parallel to one another, so as to enclose a distorted rectangle half a metre broad. Particulars of these are entered in the last line of the above table. The electrostatic capacity between one wire and the other was 147 centimetres.

43. A few rough preliminary experiments with these alternative paths were made to begin with, when it was noticed that the B spark was affected by the presence or absence of an opaque partition between it and the A spark, and not only an opaque partition—even a glass plate made a decided difference. The B spark was longer when the light from the A spark was suffered to fall upon it, and shorter when it was screened. This is manifestly the same effect as had been previously discovered by Dr. Hertz in the course of his experiments with an induction coil. He showed that it was ultra-violet light that was most effective in helping the passage of a spark, and hence the action of the glass screen.

The experiment is interesting now as proving that the A spark occurs infinitesimally before the B spark; sufficiently before it for light to have time to travel the interval between the two, though not necessarily any more than this. A screen of black card was now arranged so as to screen off the B knobs from the light from A. The varying illumination of the day was not found to make any appreciable difference, so the window light was ignored.

44. A systematic set of experiments was now made. The A knobs were set permanently 1·35 centimetre apart, and the B knobs adjusted by their micrometer-screw until about half the sparks failed and half passed. Their distance apart was then read, and the discharger A shifted to a fresh position (1, 2, or 3 in the above diagram), always keeping the A spark-length 1·35. Then B was adjusted again, and so on. The following is a record of the readings :—

Alternative path.	Length of B spark for different positions of A.		
	Position 1.	Position 2.	Position 3.
None	·638	·638	·638
No. 5 copper	·288	·210	·148
No. 2 iron	·271	·163	·090
No. 2½ brass	·269	·170	·105
No. 18 iron	·290	·120	·056
No. 18 copper	·310	·148	·148
No. 40 copper	·300	·275	·173
No. 24 brass	·260	·200	·128
No. 25 iron	·275	·068	·078
No. 23 copper	·291	·245	·175
"Longer leads"	·338	·183	·183
None	·525	—	·523

The iron conductors gave the sharpest and most definite value for the B spark-length, and the coppers gave the least definite value of all the alternative paths. When no alternative path was used the critical spark-length was much more vague, considerable variation being possible before the B sparks either wholly failed or always passed.

45. Next day the retort holders were removed from the jars so as to get rid of a possible effect of their capacity, and the jars were mounted on paraffin blocks instead; but when no alternative path was used their outer coatings were connected imperfectly by a wooden penholder or something of the sort laid across them.

The B interval was now usually adjusted until the sparks there were just ceasing, instead of being half-and-half. The same Voss jars were used, and A was still 1·35 centimetre. The following table shows the result :—

Alternative path.	Critical length of B spark for different positions of A.	
	Position 1.	Position 3.
None	·800	·745
No. 25 iron	·330	·100
No. 5 copper	·345	·100
No. 2 iron	·323	·118
No. 25 iron	—	·173 Unilluminated.
„ „	—	·293 With magnesium burning close to.
„ „	—	·275 Not screened from view of A spark.
„ „	—	·243 Screened off again.
Longer leads	·550	·323
Longer leads with far ends disconnected	·400	·300
Longer leads with ends joined again	·563	—
Ditto	·580	Sparks just ceasing.
Ditto	·450	Sparks about half-and-half.
Ditto	·240	Sparks never failing.
None	·800	Sparks just ceasing.

The discharger A was then removed from any of its three regular positions, and put right away at the end of the "longer leads." In this case an A spark 1·35 centimetre long could not be obtained, by reason of leakage; so it was shortened to ·97, and the following readings taken. The B spark was now relatively enormous when there was no alternative path, although A had been so much shortened.

Alternative path.	Critical B spark, with A at far end of leads.
No. 25 iron	·040
No. 5 copper	·031
None	1·620
No 2 iron	·028

As a variation the A discharger was restored to its old position, A_1, and the B knobs put right away at the end of the longer lead. The A spark being still ·97, the following readings were taken :—

Alternative path.	Length of B spark at far end of leads.	
	A in Position 1.	A in Position 3.
None	·271	·430
No. 25 iron	·069	·054

It must be noted that the here used A spark lengths, 1·35 and ·97 centimetres, become, when reduced to flat plates, 1·1 and ·85 respectively.

(To be continued.)

REVIEWS.

La Telegraphie Actuelle. By L. Montillot. (Baillière et Fils Paris, 1888.)

In this work of 330 pages and 131 cuts the author makes a bold and not altogether unsuccessful effort to give a clear, if in parts condensed, description of the telegraph lines, system of working, and instruments in use in France, together with some

Digitized by Google

brief reference to apparatus invented and used in other countries.

M. Montillot is connected with the Department of Military Telegraphs, and is at the same time professor at the Saumur Cavalry School, and his book is in parts a *résumé*, and in parts an extension, of lectures delivered in these capacities. It is written in such a style that "he who runs may read," and, what is more, understand the general outline of the telegraphic and telephonic applications of electricity, and is, therefore, specially suited for that general public which, not having time or opportunity of going very deeply into the study of electricity, is yet interested sufficiently to wish to know something of the means by which such results as it is familiar with are obtained.

In Chapter I. we are told how an aerial line is constructed, and a good description is given of Dr. Boucherie's process for injecting poles with sulphate of copper. This is the only "authorised" system in France, and has been found to give better results than treating them with chloride of zinc, creosote, linseed oil, tar, or by partial carbonisation.

Various forms of insulators are mentioned, but there is no reference to Johnson and Phillips's, or other forms of the "fluid insulator," which have given such excellent results in this country, on the Italian coast-lines, and elsewhere, but which are apparently officially unknown to the French administration. Several pages are devoted to an explanation of the *modus operandi* followed in France, Germany, Belgium, and England for laying underground lines, and brief reference is made to submarine cables, and to the bridge, loop, and Lumsden fault tests. In following chapters we find descriptions of various forms of voltaic cells, the Wheatstone bridge, resistances and condensers. Breguet's alphabetical instruments, and various types of Morse recorders, are fairly explained, and instructions given for setting them up.

No less than fifty pages are devoted to a comprehensive description of the Hughes type-writer, from its origin, through successive developments, to its present form. Twenty pages are given to the Wheatstone, and we then, after brief mention of the Meyer instrument, come to the most remarkable achievement of French telegraphy, the Baudot, which was the natural sequence of the Meyer, and which, in France, has quite supplanted its predecessor.

These instruments are but little known outside a limited circle in England, and a few words about the first of them may not be out of place, though anything like a full description of either would not be practicable within the limits of the present notice.

M. Meyer's invention is based upon the fact that in Morse transmission, owing to the necessity for spaces separating the different signals of the same letter, between letters, and between words, rather more than fifty per cent. of the time occupied in signalling is lost, and he tried to devise a means whereby this lost "space time" could be utilised for the transmission of a different set of signals. In the simplest form of M. Meyer's apparatus there are four keys, four receivers, and a distributor or current divider at each end of the line. The receivers and the divider are governed by the same clockwork movement, and synchronism is maintained between them and the corresponding instruments at the distant end of the line.

The key is formed of eight contacts, putting the battery in communication with the divider, which is an ebonite disc, each quarter section of which is formed of four sets of three contacts, two of which are by means of a revolving switch put in momentary connection with the line, while the third gives a passing discharge to earth. By means of the key any letter of the Morse alphabet can be formed in advance, stored up on the divider, and carried on to the line at the moment the switch passes over the contacts. The line is by means of the third contact put to earth between each signal. Supposing that all the four keys are used, the signals made from them on to the divider are taken up in succession by the revolving switch, passed over the line, and at the distant end a second divider distributes them to the receiving instruments.

A thorough description of the Meyer system will be found in the *Zeitschrift für Elektrotechnik*, 1885, with numerous cuts, illustrating the mechanical details of this ingenious invention.

M. Baudot, starting with the idea of reproducing in type the Morse signals received by the Meyer, was led step by step to the production of the beautiful, though complex instrument which, first exhibited at the Paris Exhibition of 1878, has since come into use on most of the busy circuits in France, and is likely to become the favoured multiplex system over the greater part of the European Continent.

M. Montillot, after giving over thirty pages to a description of the Baudot, winds up by saying, "In so limited a space we have been unable to enter into the minor details of so complicated an apparatus as the Baudot. There remains much to be said of the means used for regulating or modifying the movements of the different parts of the instruments, and for enabling them to work under the ever-varying conditions of long lines. . . . Nothing can replace the instrument itself for those who wish really to thoroughly master all its details; and for such a careful and thorough dissection of it alone will enable them to obtain a perfect comprehension of all its parts." We venture to think, however, that a very fair idea may be obtained from M. Montillot's work. A good description of both Meyer and Baudot's invention will also be found in "Les Télégraphes," by the late M. Ternant, published by Hachette and Co., Paris.

In Chapter VII., astatic, marine, and ordinary signalling mirror galvanometers are described, together with Sir W. Thomson's recorder. The woodcut illustrating this latter is faulty in several parts, and it seems strange to find the instrument itself spoken of indifferently as a "recorder" and a "siphon."

Estienne's modification of the Morse is favourably noticed, and as a successful experiment of it is stated to have been made upon the Brest-St. Pierre cable, it is likely we shall hear more of it before long.

The various duplex arrangements of Messrs. Stearn, Orduna, Brasseur, and De Sussex receive due mention. We are somewhat astonished to find no description of Muirhead's or Ailhaud's, at any rate by name, although what M. Montillot terms "duplex by differential coil," and illustrates as applied to a Morse line, may be the latter under a modest incognito.

The two concluding chapters are devoted to summary descriptions of the various forms of telephones most in use in France, and Van Rysselberghe's arrangement for the simultaneous use of the same line for telephonic and telegraphic purposes.

That he may remain true to the title of his book, M. Montillot closes it by reference to Mr. Ader's newest idea on the subject of working submarine cables by telephones which was described and illustrated in *The Electrician* of March 30, 1888, p. 569. M. Montillot says:—"We have already stated that all attempts to work cables by means of telephones had failed, owing to the retardation, and to the fact that the propagation of the current through these long lines was effected in a manner exactly the reverse of that required for telephonic vibrations. To obtain any result, then, it became necessary to resort to artifice. Mr. Ader proposes to obtain audible signals by means of telephones, using positive and negative currents, exactly in the same manner as is now done for the mirror or recorder. At the receiving end of the cable the line is forked, and joined to two make-and-break coils, giving by their vibrations sounds which can be easily made distinguishable one from the other. The other ends of these coils are joined to two telephones connected, one to the positive the other to the negative poles of a battery, the middle of which is to earth. It follows that the current coming *from* the line flows through the two make-and-break coils, the two telephones and both sides of the battery before finding an earth. But whatever be the line current, it meets in one of the branches of the receiving circuit a current of the same name, and in the other branch an opposing current; there is consequently in one branch a strengthening of the arrival current, and in the other a weakening of it, so that in one telephone is heard a strong tick, in the other a weak one, and this latter can by suitable adjustment be almost entirely suppressed. If a positive current produces a strong sound in the right hand (or ear) telephone, a negative current will act similarly on the left-hand one; in short, the currents are thrown on to the line at the home end as if intended to be read off on a recorder. At the distant end they are halved by the vibrators, strengthened on one side of the local battery, and weakened on the other. The telephones being

Digitized by Google

specially regulated to respond one to the positive the other to the negative currents, sound reading becomes perfectly easy. We are unaware if this new plan has been practically applied; but it would seem to have a great future before it, if it were completed by a simple system enabling the transmissions to be controlled and checked."

"La Télégraphie Actuelle" will be found a useful little book by English students desirous to familiarise themselves with the French methods of working, and at the same time to learn some of the technical expressions with which they should be familiar before attempting the study of more advanced books.

Puck's Girdle. Edited by C. ARMSTRONG. (London: Wyman and Sons.)

Under the title of "Puck's Girdle," Mr. C. Armstrong, of the Edinburgh post office, has gathered together some "Gleanings from the Postal and Telegraph World" in the form of a shilling Christmas annual, the contents of which ought to prove attractive to readers outside that particular world, as well as inside.

Calendar for Electricians, 1889. By F. UPPENBORN. *(Kalender für Elektrotechnikes,* 1889.) (R. Oldenbourg, München und Leipzig.)

We have received from the publisher the 1889 issue of the above, already in its sixth year. As it is pretty widely known, it is hardly necessary to say it aims at being a sort of annual Munro and Jamieson. Some of the matter would perhaps be more in place in a text-book, and might with advantage be left out in a publication which should be as small as possible, consistent with fulness. The legitimate pocket-book matter, however, is generally complete and well chosen.

A Workman's Electric Lighting Vade Mecum. By S. v. GAISBERG. *(Tascenbach für Monteure Elektrische Beleuchtungs Anlagen.)* (R. Oldenbourg, München und Leipzig.)

This practical little work, now in its third edition, is apparently written by a man who has himself had to teach workmen. In plain and simple language, it contains good sound information, and is just the book which, if put into the hands of an intelligent man in charge of an installation, should make him capable both of keeping everything ship-shape, and putting right anything which goes wrong. It should also be valuable to the mechanical engineer, when, as frequently happens, he has an installation in his factory without skilled electricians on his staff.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

SECTION II.—ELECTRO-MAGNETIC FIELDS.

(Continued from page 193.)

141. *Kapp Lines.*—At this stage it may be well to allude to the English unit of magnetic induction introduced by Mr. Gisbert Kapp, and now largely in use by manufacturers of electrical machinery. A new unit line of force, equal to 6,000 C.-G.-S. lines, is adopted, and the sectional area of iron is taken in square inches instead of square centimetres. The new unit of induction is therefore one of these assumed lines per square inch section, and is generally known as one Kapp line per square inch, or one English unit of induction.

The number 6,000 is composed of two factors, viz., 60, which enables the formula for the E.M.F. produced in a rotating armature to be expressed in revolutions per minute instead of per second; and the factor 100, which brings the measurement of induction down to figures in the tens instead of thousands. Now, if we divide 6,000 by 6·4514 (the number of square centimetres in one square inch), we have the number of C.-G.-S. lines per square centimetre equivalent to one Kapp line per square inch = 930·03, or say 930; therefore,

1 Kapp line per sq. in. = 930 C.-G.-S. lines per sq. cm.,

or 1 English unit = 930 C.-G.-S. units of magnetic induction.

For the purpose of comparison the vertical ordinates of the last curve have been reduced to Kapp units by dividing the values of **B** by 930 (Fig. 123). The highest induction arrived at in this specimen of soft iron is seen to be 18 lines, and the practical saturation 17·2 lines (16,000 C.-G.-S. lines). In the previous paragraph we noted that there was no absolute limit to induction, and that 20,000 C.-G.-S. units (= 21·5 Kapp units) might be considered a fair average induction in machines whose armatures were of well-annealed wrought iron. The extremely high value reached by Prof. Ewing of 45,350 C.-G.-S. lines with wrought iron is equivalent to 48·7 Kapp lines. One or two examples quoted from descriptions of dynamos in which the induction is expressed in these units may render their practical application intelligible. For instance, in *The Electrician*, Vol. XX., page 35, we find:—

"The cross-sectional area of the magnet bars is 30 square inches, and the total cross-sectional area of actual iron in the armature is 20 square inches. The total excitation of field-magnets at full load is 12,130 ampere-turns, and the total strength of useful field is 378 lines (English measure). The density in the magnet cores is therefore 12·6 lines per square inch, and in the armature core 18·9 lines per square inch."

Again, on page 162, in the description of another machine: "The field strength in the core, according to the figures supplied us, works out at a very high figure, viz., to 23·6 lines per square inch." These calculations are on the basis of Mr. Kapp's formulæ given in his Paper on "The Predetermination of the Characteristics of Dynamos" (*Journal* Soc. Tel. Eng., No. 64), and take into account magnetic resistance and leakage. In that Paper Mr. Kapp gives the average

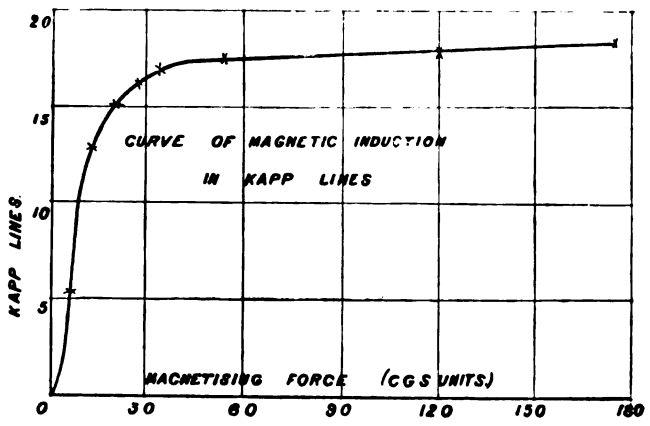

FIG. 123.

practical saturation values of induction derived from numerous data and experiments on machines, pointing out that the figures given are by no means the highest obtainable with exceptionably good iron. These are as follows:—Armatures built of well-annealed charcoal iron wire 25 lines per square inch, armatures built of discs of the same iron 22 lines, field-magnets of hammered scrap iron 18 lines. Multiplying by 930 we find these are equivalent to 23,250, 20,460, and 16,740 C.-G.-S. lines of induction respectively. Considerable exception to these English units was taken by scientists at the time of their introduction two years ago, chiefly on the ground of the necessary transposition of coefficients used with formulæ based on the inch-minute system into their value on the centimetre-second system. Mr. Kapp's reply to this and other objections (Society of Telegraph-Engineers' meeting, Dec. 2nd, 1886), was as follows:—"I use minutes because everybody is accustomed to counting revolutions per minute, and anybody quite unacquainted with French measure can work my formulæ, and would at the same time see what he is doing. The figures are of reasonable magnitude, and present to those who use them a definite meaning. They know what is meant by 17 lines to the square inch, but if we talk of 15,800 to the square centimetre a greater mental effort is required to grasp the meaning. . . . The translation from it to C.-G.-S. units is really not such a difficult matter as we are told, and with a little training one could get to manage either system equally well; but we have to talk to our workmen, and then we could not use grammes, centimetres, and seconds. We must give them figures in the usual English measure, and therefore it saves labour if we make the calcula-

Digitized by Google

tions in a system where the figures are of reasonable magnitude and directly applicable to the various purposes of the workshop."

142. *Magnetic Permeability.*—To denote the degree to which iron and other magnetic metals permit lines of magnetic induction to *permeate* through their substance, under the action of a given magnetising force, the term "*permeability*" has been applied. The permeability of a specimen of iron is said to be high if it will permit the flow of a large magnetic induction through its mass for the expenditure of a small magnetising

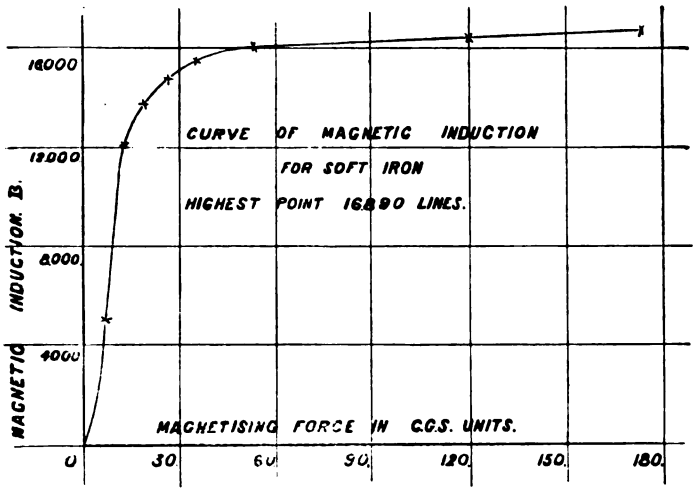

FIG. 122.

force, and *vice versâ*. In other words, magnetic permeability is the ratio between magnetic induction **B** and magnetising force **H**, and is usually denoted by the Greek letter μ. By inspection of the curves it will be seen that this property, like that of susceptibility, is not a constant quantity for any given kind of iron, but depends on its magnetic condition. For instance, in the curve given (Fig. 122) when the induction is between the limits of 4,000 and 12,000 C.-G.-S. lines, the permeability is fairly constant at about 800, but gradually falls to 300 at 16,000 lines, and ultimately to 100. In softer specimens of iron the permeability may reach 3,000 or 4,000.

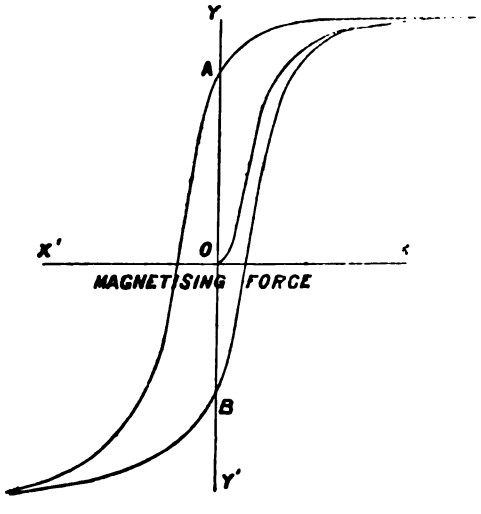

FIG. 120.

The meaning of these figures may be better appreciated by considering them as indicating the permeability of iron with reference to that of air. In a magnetising coil, with no iron present, the induction produced in the air space in the interior is identically the same as the magnetising field, and, therefore, the ratio of the two, *i.e*, the magnetic permeability of air, is equal to unity. The number indicating the permeability of iron is therefore the number of times its permeability exceeds that of air. When iron is acted upon by an alternating or increasing and diminishing magnetising force, its permeability, when not near saturation, is constant. The parallelism of the ascending and descending lines in the cyclic curve of magnetisation (Fig. 120) shows the susceptibility to be constant for low magnetising forces, and it follows that the permeability is constant. The exact relation between permeability and susceptibility may be found by taking the fundamental formula given in para. 139.

$$\mathbf{B} = 4\pi\mathbf{I} + \mathbf{H},$$

and dividing each side by **H**; we then have

$$\mu = 4\pi\kappa + 1,$$

or Permeability = 1 + Susceptibility × 12·57.

We may regard the term permeability as meaning the conductivity of iron to lines of force, in the same way as we speak of the conductivity of iron to the passage of electric currents; with this important difference, however, that while the electrical conductivity of iron at a given temperature remains constant for all intensities of current, its magnetic permeability decreases to a very marked extent as the intensity of magnetic-field or number of lines through it is increased.

If we pass an electric current through a piece of iron wire, and gradually increase the intensity of current until the wire is red-hot, the conductivity of the metal will have undergone a considerable change. As soon as the intensity of current is sufficient to cause the slightest rise in temperature of the iron, the conductivity of the latter commences to diminish, and beyond this point any increase in the flow of current causes a rapid diminution of the conductivity. This decrease of conductivity in an electrical circuit, on increasing the intensity of current through the conductor, may be taken as being somewhat analogous to the decrease of permeability in a magnetic circuit, on increasing the intensity of magnetic flow, or induction through the iron.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714.

All Communications to be addressed to "The Electrician," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician."

All letters intended for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.

"The Electrician" is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.

SPECIAL NOTICE.

Owing to the increase in the number of pages of "The Electrician," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
„ Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"The Electrician" offers exceptional advantages to Advertisers. **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Trade Advertisements *intended for the current issue must be handed in not later than First Post on Thursday morning.*

Small Prepaid Advertisements *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"The Electrician" Printing and Publishing Company (Limited) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

The Electricians' Directory.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "The Electrician" Electrical Trades' Directory and Handbook. *The Directory was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 will SHORTLY BE READY.

1888.

The historian of the future will probably date the introduction of electric lighting upon a grand scale from the year 1888, and from the passage of the Electric Lighting Amendment Act; and in commencing our review of the electrical events of the year this is naturally the one which first engages our attention. This important measure was introduced into the House of Lords by Lord Thurlow in March, and finally passed into law on 18th June. It is well known that the Act provides for an extension of the period before the compulsory purchase clause of the Act of 1882 becomes operative from twenty-one to forty-two years, and it also modifies the terms of purchase in favour of the contractors by the introduction of the phrase, "fair market value." What is the exact bearing and value of the last-named concession still remains to be discovered. The acceptance of this, or some very similar measure of relief, having long been regarded as a foregone conclusion, even at the commencement of the year many schemes were already afoot for the establishment of Central Lighting Stations and for the formation of Electricity Supply Companies, chiefly within the Metropolitan area. The passing of the Act was therefore immediately followed by an outburst of activity in this direction, and it is satisfactory to note that up to the present the movement has, upon the whole, proceeded upon perfectly sound and healthy lines. Whilst there has been no sign whatever of the inflation which characterised the imperfect schemes and preposterous financial ideas in vogue in 1882, yet there has been little or no difficulty in obtaining financial support for the majority of the undertakings now in progress. In more than one instance—including that of the largest scheme afloat—the whole of the capital has been raised by private subscription, and the public have not even been asked to contribute; in other cases a large proportion of the shares are held by leading companies, or firms of electrical engineers. This must certainly be considered a healthy and satisfactory feature.

On taking a general survey of the various projects in hand one cannot help being struck by the singular diversity of operations which they present. Out of the ten or a dozen

Digitized by Google

stations in London now either in active existence or which are in a more or less advanced stage of progress, it is a remarkable fact that no one system can claim more than two examples at the most. But as we shall devote a separate article to a consideration of the development of electrical engineering during the year, we do not here intend to enter upon a technical description of these schemes; so that we shall confine ourselves to some general remarks upon the recent history of the movement and the present aspect of affairs. Excluding two small arc-lighting stations of the Pilsen-Joel Company and one Fyfe-Main station now being constructed at Brixton, the remainder of the London installations may be broadly divided into storage-battery and alternate-current transformer systems. Of the battery stations there are four in hand, exemplifying three different methods of utilisation. The Chelsea Supply Company, when its works are ready, will employ battery sub-stations provided with the ingenious automatic arrangements which have been worked out by the officers of the E.P.S. Company. The Cadogan Company utilises the highly interesting and remarkable distributor of Mr. H. Edmunds. These two are both high-tension "transformer" systems, whilst at Kensington Court and also at Whitehall we have genuine low-tension network systems, in which the batteries are confined to the engine-room, and are used only for storage purposes. So far as Kensington Court is concerned, it is probable that if the experience of Mr. Crompton at Vienna should prove sufficiently favourable, his method of battery sub-stations will be introduced at a later stage. The adoption of secondary batteries upon this extensive scale goes far to show that the storage cell, as adapted to electric lighting purposes, has now assumed a form which entitles it to some degree of confidence.

But interesting and hopeful as these schemes most certainly are, it is to alternate-current transformers that we must turn in order to observe the grandest and most striking features in the present development of electric light engineering. The Grosvenor Gallery station, with its 30,000 lamps, is a *fait accompli* which already takes rank with the most important even of American stations. The Bond-street station is, however, but a comparatively insignificant item in the vast scheme which the London Electric Supply Corporation is actively pushing forward. As soon as the gigantic designs of Mr. Ferranti have been realised, the monumental station at Deptford will supply a whole series of sub-stations—of which the Grosvenor Gallery will be one—with an alternating current at 10,000 volts potential, which will thence be distributed at a lower potential throughout an area which, if the hopes of the promoters are realised, will practically extend over the whole of London proper. At the end of December the building operations at the Deptford station are rapidly approaching completion; most of the boilers have been fixed, and the work of erecting the engines will shortly commence.

The Metropolitan Electric Lighting Company have likewise embarked upon an ambitious programme, but instead of placing their eggs all in one basket, they have decided to create a number of separate stations in various parts of Central London. The City is to be provided for by a station at the southern end of Southwark Bridge, a second station will be built on the same side of Waterloo Bridge, a third in Sardinia-street, near Lincoln's Inn-fields, and a fourth in Marylebone. Alternate-current transformer methods will be employed in every case, but up to the present time the only contract which has been settled is one with the Westinghouse Company for the Sardinia-street station. The Metropolitan Company has also taken over the Whitehall Mansions installation. The House-to-House Electric Light Supply Company has a station, now almost ready for work, at West Brompton, where the Lowrie-Hall alternate-current transformer, a system which has proved so successful at Eastbourne, is employed. This company, in common with most of the others which have been alluded to, has given notice to the local authorities of its intention to apply for Provisional Orders over a considerable portion of the Metropolitan area. A Mordey alternator plant is also at work in a small central station in Oxford-street, which is in private hands.

Turning to the provinces we do not find so much progress to record. In Liverpool, where Messrs. Holmes and Vaudrey have had a small central station at work for several years, two other stations in the hands of the same firm have been recently completed, and a total of 3,000 lamps is now supplied over an area which includes the chief business part of the town. All these belong to the low-tension direct-current class. The Bradford Corporation have contracted with Messrs. Siemens for the supply and erection of low-tension direct-current plant; and this is noteworthy as being the first instance of a Municipal Central Electric Lighting Station in this country. Here, however, the building operations are still incomplete. The Corporations of Dublin and of Swansea have applied for Provisional Orders to enable them to follow suit. The Leamington installation, which at first laboured under some difficulties, has now been running without any hitch during the whole twelve months, though the public are still dissatisfied with the street lighting. At Brighton the interesting and successful multiple-series system, which had been cleverly worked out by Mr. Arthur Wright, having arrived at a point where it did not lend itself to further extensions, is being replaced by an alternate-current system. At Bath Mr. Massingham has under weigh a contract to light the streets with Thomson-Houston arcs, power being derived from the waters of the Avon, whilst the Taunton station continues to do satisfactory work. At Barnet Mr. Joel has started an installation for street-lighting with Bernstein lamps, but owing apparently to an attempt to carry out the work in too short a time the result is not at present satisfactory. A small Ferranti station was started in Chatham in the middle of December. Adding some others of minor importance, the total number of central stations in actual operation in this country is now twenty-six, of which eight were opened during the past twelve months. There are also seventeen stations actually in process of construction and eleven others projected, including only those whose prospects of realisation seem reasonably assured.

One of the natural results of the extensive preparations for central station lighting has been, so far as London is concerned, to place some check upon the increase of isolated stations. But, notwithstanding this, the general demand for electric lighting plant and apparatus of all descriptions has undoubtedly been greater this year than at any previous period, and still continues to improve. Broadly speaking, it may be said that all the leading makers are now well employed. Overtime working and plans for the extension of works are reported in several directions. The improvement is specially felt by the manufacturers of insulated wire, switches and cut-outs, electroliers, &c., in which class a very extensive and profitable trade is now being done; in fact, for the makers of all these minor adjuncts the prospects are very good indeed.

The enforcement and interpretation of the Electric Lighting Acts having been entrusted to the Board of Trade, that body finds itself charged with a task of the most onerous and responsible character. One of the most important of its duties is the framing of rules and regulations for each undertaking, in order to safeguard the interest of the consumers as well as of the general public; but it has wisely decided not immediately to enforce any general code. Two questions of the first

Digitized by Google

degree of importance in the administration of the Act remain at present in a state of some uncertainty. First, as to how far the application of the Act is compulsory where the Local Authority is willing to allow mains to be laid. This question has arisen at Ipswich, where Messrs. Paris and Scott are erecting a central station, and the Board in the early part of December expressed their inability to come to an immediate decision on the point. Secondly, in what degree does the possession of a Provisional Order confer a monopoly of the power of laying mains in the scheduled district? At the end of November this serious question assumed an acute form in Chelsea, where the opinion of the Vestry differs from that of the Chelsea Electricity Supply Company. The point is one of fundamental importance, but no decision has yet been arrived at. The Board of Trade has recently announced that it does not intend to issue any more "Licenses" for the Metropolitan area, so that further extensions will have to be by way of Provisional Order.

Coming now to the application of electricity to the transmission of energy, we cannot report much progress. Large numbers of electric motors have undoubtedly been sold during the year, but there is little of general interest to record. The utilisation of motors in connection with central station currents is still a thing of the future so far as this country is concerned. No new electric tramway has been started during the year, although several experimental cars have been running. Electric launches have appeared on the Thames on several occasions, and Messrs Immisch and Co. are understood to be building quite a number of boats of this description for next summer. It has been decided to work the City and Southwark Subway by electricity, but the contract has not yet been assigned. The directors of the Metropolitan Railway have also entered into negotiations with the Electric Traction Company in connection with the application of electricity to the underground lines—a consummation most devoutly to be wished! Some interesting and successful work has been done in connection with the use of electric motors in mines, principally by the firm of Immisch and Co. We are now looking forward to the introduction of alternate-current motors, which, if thoroughly successful, have undoubtedly a great future before them. The progress which has been made in this direction during the past twelve months has been of a highly remarkable character, and leaves little doubt of the ultimate solution of the problem—perhaps in more ways than one.

The attention of both scientific and practical men has been strongly drawn to the very important question of Lightning Conductors, and incidentally, therefore, to lightning. At this time last year we had scarcely realised how very shadowy is our real knowledge of these subjects. The superiority of copper over iron as the material for lightning conductors was understood to have been fully proved by the researches of Prof. Hughes, and it was not until Prof. Silvanus Thompson drew the attention of the Physical Society in January to the influence of the melting point of the metal that the slightest misgiving as to the soundness of this conclusion was entertained. In March, however, Dr. Oliver Lodge, whilst engaged in preparing for the delivery of the Dr. Mann lectures before the Society of Arts, made a discovery whose full significance can hardly as yet be realised. On offering a Leyden jar the alternative of effecting its discharge either across an air gap or by way of a closed metallic circuit, Dr. Lodge discovered that under certain circumstances a short and stout bar of copper presents a greater obstacle to the discharge than does a thin iron wire of much greater length. This singular and paradoxical fact has formed the starting-point of a series of remarkable investigations upon the nature of the static discharge, which has directed general attention to a long-neglected branch of electrical science, and bids fair to open up a wide field for discovery—and possibly, at a later stage, for invention. Amongst other conclusions at which Dr. Lodge speedily arrived is one of the highest interest and importance, namely, that the lightning flash may sometimes assume an oscillatory character, with a period of something like one-millionth of a second. In this way it is possible to account for some at least of the vagaries of lightning, which are otherwise wholly inexplicable. But the recognition of the oscillatory discharge—first discovered by Hehnholtz in 1847, and the theorem of which was extended by Sir William Thomson in 1855—offered no immediate explanation for the preference of iron over copper; in fact, it greatly increased the difficulty of the problem, and led, for a time, to the supposition that for very high rates of alternation the magnetic permeability (and hence the self-induction) of iron is vanishingly small. Later theoretical developments have, however, enabled Dr. Lodge to show that these assumptions are not only unnecessary, but that they are actually contradicted by experiment; and to the further elucidation of this question he is devoting the remarkable Papers which are now appearing in this journal. Dr. Lodge's views have been loudly challenged by the "practical" school, who were ably led to the attack by Mr. W. H. Preece during the Bath meeting of the British Association. The discussion cannot be said to have led to any very definite result, and since that date some of the most important advances in the general theory have been made.

In the spring of the year it was suggested by Messrs. Wheatley Kirk, Price and Goulty that a way out of the difficulties which surrounded the projects which had so long been under consideration for the establishment of some kind of electrical trades association might be found by the formation of a branch or section of the London Chamber of Commerce. This happy inspiration was taken up by the leading London firms, and after one or two preliminary meetings had been held the Electrical Trades Section of the London Chamber of Commerce became an established fact. The first meeting was held on Monday, 22nd October, when a committee of thirty-three members was elected by ballot, which committee subsequently elected Mr. R. E. Crompton as their chairman, with the Earl of Crawford and Major Flood-Page as vice-chairmen. The section, which now numbers some 200 members, is divided into the following sub-sections: Telegraph Companies, Electrical Manufacturers and Contractors, Telephone Companies, Electricity Supply Companies, Consulting Electrical Engineers, General, each of which has its own special representatives on the committee. The benefit of working under the ægis of the Chamber of Commerce is already manifest, and the valuable and efficient services of Mr Kenrick Murray, the general secretary of the Chamber, is fully appreciated. Several meetings of the Sectional Committee and Sub-Committees have been held, when the affairs of the Electric Supply Companies have been the chief topics of discussion. The organisation has so far worked with admirable smoothness, and we think it will prove capable of rendering valuable service.

Under the Presidency of Mr. E. Graves the Society of Telegraph-Engineers and Electricians has completed the most active—and, perhaps, upon the whole, the most successful—year of its existence. The Society has received a larger accession of members, has held a greater number of meetings, and the average attendance has been more numerous than in any previous session. In the month of April the Council issued a set of Installation Rules, a step the propriety of which was hotly contested on the part of the representatives of some of the Fire Insurance Companies. So far, however, the appearance of these rules can scarcely be said to have led

Digitized by Google

to any practical result. The relative merits of the alternate current and the battery methods of distributing electricity have formed the principal subject of discussion during the Session, but the valuable Paper of Prof. Rücker on "Electrical Stress," and that of Prof. S. P. Thompson on "Influence Machines," have served to show that the Society does not altogether neglect the study of pure science. By an almost unanimous vote the title of the Society has now been changed to that of the Institution of Electrical Engineers.

Amongst the leading events of the year we have also to notice some topics of a less pleasant character—we refer to the costly and unhappy litigation in which several of the leading companies are involved. The action brought by the Edison-Swan Company against "Holland and Others" (*videlicet* the Anglo-American Brush Corporation) came before Mr. Justice Kay on April 17th, and occupied the attention of the Court for no less than twenty-two days. In this case it was sought to establish the exclusive right to manufacture incandescent lamps on the part of the holders of Mr. Edison's patent of November, 1879, and a subordinate claim for a monopoly of the "flashing" process was also entered for the Cheesborough patent. On 16th July Mr. Justice Kay delivered judgment in favour of the defendants in respect of the former claim, and in favour of the plaintiffs as regards the latter. An appeal was immediately entered by the Edison-Swan Company, and this came before the Court on December 1st. The argument lasted ten days, and the Court then reserved judgment, which has yet to be delivered.

On 29th June an action came before Mr. Justice Kekewich, in which Mr. Ferranti appeared as a petitioner for the annulment of the patent held by Messrs. Gaulard and Gibbs on the ground of anticipation and non-utility. After a hearing extending over eight days judgment was delivered declaring the patent null and void. An appeal was entered, which will come before the Courts in January.

A similar action for the voidance of a patent has been brought in the Scotch courts by Messrs. King, Brown and Co., of Edinburgh, who seek to demolish the claim of the Anglo-American Brush Corporation to a monopoly of compound winding; the ground chiefly relied on is an alleged anticipation by Mr. C. Varley. The case commenced on Nov. 27th, and has not yet been concluded.

(To be continued.)

SUMMARY OF ELECTRICAL EVENTS FOR 1888.

JANUARY.

Presidential Address of Mr. Edward Graves to the Society of Telegraph-Engineers.
The Metropolitan Board of Works resolve to permit Mr. W. Webster, jun., to carry out his electrical purification of sewage experiments at his own expense at Crossness.
Sir John Pender made a K.C.M.G.
M. Raynaud, Director of the Paris Telegraph School, assassinated.
New York Special Commission report in favour of death by electricity.
Launch of the Eastern Telegraph Company's steamer, "Amber" (19th).
Opening of the New York Electric Club.
The Volta Prize awarded to M. Gramme.
Trial of the Lineff and Jones Electrical Tramway at Chiswick (25th).

FEBRUARY.

Mr. Gisbert Kapp's Paper "On Alternate-Current Transformers" read before the Society of Telegraph-Engineers (9th).
Lighting of the Great Northern Railway Company's trains by electricity.
Mr. Raikes informed the House of Commons that the Government did not intend to renew the concession of the Submarine Telegraph Company (18th).
Meeting of the Association of Edison Companies at Chicago.
Meeting of the National Electric Light Association at Pittsburg.
The House-to-House Electric Light Supply Company registered.

MARCH.

Registration of the Gülcher (New) Electric Light and Power Company.
Second Reading of the Electric Lighting Act (1882) Amendment Bill in the House of Lords (5th).
Mr. Raikes informed the House of Commons that the Government contemplated no scheme for purchasing the telephones (6th).
The proposed contract with the Anglo-American Brush Corporation for lighting the City finally rejected.
Large contract of the Anglo-American Brush Corporation with the Australasian Brush Electric Light, Power, and Storage Company to light the Melbourne Exhibition; 800 arc and 3,000 incandescent lamps.
Dr. Oliver Lodge delivered his lectures on "The Protection of Buildings from Lightning" before the Society of Arts.
Death of M. Richard, the eminent French telegraph engineer.
Completion of the Vevey-Montreux Electric Tramway.
Decision of the Supreme Court of the United States, upholding the validity of the Bell Telephone Patent.
Committee of Investigation appointed by the shareholders of the Pilsen-Joel Company (13th).
Washington Capitol struck by lightning.
Paper on "Electrical Stress" read before the Society of Telegraph-Engineers by Prof. Rücker and Mr. C. V. Boys (22nd).
Meeting of the Maxim-Weston Company; a committee of five appointed to inquire into the affairs of the company (28th).
The use of gas in the Madrid theatres prohibited, and the adoption of the electric light within six months made compulsory (31st).

APRIL.

Paper read by Mr. J. W. Howell, at a meeting of the American Institute of Electrical Engineers, on "The Maximum Efficiency of Incandescent Lamps."
The Belgian Society of Electricians offer a prize of 250 francs for the best essay on the elementary principles of electricity.
Adoption of the Electric Lighting Scheme by the Gas Committee of the Bradford Corporation.
A Central Laboratory of Electricity inaugurated at Grenelle.
Report of the Pilsen-Joel Company Committee of Investigation (12th).
Issue of the revised Fire Rules of the Society of Telegraph-Engineers.
Paper on "Central Station Lighting, Transformers *v.* Accumulators," read before the Society of Telegraph-Engineers by Mr. R. E. Crompton.
The action brought by the Edison-Swan Company against the Anglo-American Brush Corporation came before Mr. Justice Kay (17th).
The New York Assembly passes a Bill in favour of Capital Punishment by Electricity, by 87 to 8 votes.
Lord Crawford's Electric Lighting Bill read a second time in the House of Lords (17th).
Death of Mr. T. R. Crampton, M.I.C.E. (19th).
Dinner to Sir John Pender, K.C.M.G. (23rd).
Telephone Union (Limited) registered (23rd).
Report of the Maxim-Weston Company Committee of Investigation (25th).
United Kingdom Telephone Union (Limited) registered on the (28th) with a capital of £10,000,000.

MAY.

International Convention for the Protection of Submarine Cables came into force (1st).
Completion of the largest arc light (6,000,000 candle-power) in the world at the St. Catherine's Lighthouse, Isle of Wight.
Death of Sir Charles Bright (3rd).
Lord Thurlow's Bill read a second time in the House of Commons (8th).
Opening of the Glasgow Exhibition.
Republication of the Paris Municipal Tariff.
The first words spoken over the Paris-Marseilles telephone line (562½ miles) (14th).
The Barnet Local Board conclude a contract with Mr. H. F. Joel for the lighting of their town by electricity.
The Bath Town Council resolve to advertise for tenders for electric lighting (22nd).
Paper on "The Influence Machine from 1788 to 1888" read by Prof. Silvanus P. Thompson before the Society of Telegraph-Engineers (31st).
Local Government Board Inquiry into the Bradford Electric Lighting Scheme.

JUNE.

Visit of the Cheltenham Town Council to the Eastbourne Central Station.
Amalgamation of the Edison Continental Company with the Swan Company, so far as concerns the French lamp patents (8th).

Digitized by Google

Lord Thurlow's Bill passed through Committee (11th).
Local Government Board authorise the Bradford Electric Lighting Scheme (12th).
Lord Thurlow's Bill read a third time in the House of Commons (14th), and the Commons' Amendments subsequently agreed to by the Lords (18th).
Deputation to the Postmaster-General in support of the United Telephone Company's Bill.
Opening of the Gaulard-Gibbs *v.* Ferranti case, before Mr. Justice Kekewich (29th).
Paper by Mr. F. J. Sprague "On the Solution of the Municipal Rapid Transit Problem" read before the American Institute of Electrical Engineers.
The Electrical Purification Company (Limited), registered (23rd), formed to acquire Mr. William Webster's patents relating to the Electrical Treatment of Sewage.

JULY.

The Electric Launch "Malden" at Henley Regatta.
Judgment given for the plaintiffs in the Ferranti *v.* Gaulard-Gibbs case (9th).
Meeting of the Members of the London Chamber of Commerce interested in the proposed Electrical Section (13th).
Judgment given in the Edison-Swan *v.* Anglo-American Brush Corporation action for the defendants as regards the Edison Patent, and for the plaintiffs as regards the Cheesebrough Patent (16th).
Nomination of the Organisation Committee of the International Congress of Electricians (16th).
Adoption of the Electric Light Scheme at Bath (24th); Mr. Massingham's proposals accepted.
The Organising Committee of the International Congress of Electricians elect an executive committee (24th).
The Hotel de Ville, Brussels, struck by lightning (26th).
Further meeting of the Members of the London Chamber of Commerce interested in the proposed Electrical Section (27th).
Death of Mr. Hiram Sibley.
Formation of the Metropolitan Electric Supply Company, with a capital of £500,000.
The Paris Municipal Council vote funds for the establishment of a Central Station at the Halles Centrales.
The firm of Crompton and Co. converted into a limited liability company.
The Corporation of Wellington, N.Z., accept the contract of the Gülcher Company to light that city by electricity.
Experiments by Mr. Harold P. Brown at Columbia College on the death-dealing properties of the electric current.
The Chelsea Electricity Supply and the Cadogan Electric Light Companies registered.

AUGUST.

Mr. Hugh Watt, M.P., resigns his post as Chairman of the Maxim-Weston Company.
The Thomson-Houston Automatic Current-Regulating Patent upheld in the States.
Meeting of the Edison Association at Nantasket Beach, near Boston.
Failure of the Westinghouse Company to sustain the Gaulard-Gibbs Patent in the States.
Purchase of the Tesla Motor Patents by the Westinghouse Company.
Issue of an order by the Turin authorities directing that no theatre be allowed to remain open after the 1st November unless lit by electricity.
Death of Prof. Edlund (10th).
Meeting of the American Association for the Advancement of Science at Cleveland (15th).
Death of Lord Alfred Paget, C.B. (25th).
Meeting of the National Electric Light Association in New York (29th, 30th, and 31st).

SEPTEMBER.

Cessation of the Atlantic Cable Rate War (1st).
Death of Prof. Clausius.
Third Annual Meeting of the Victorian Electric Telegraph Association at Melbourne.
Meeting of the National Telephone Exchange Association in New York (4th and 5th).
Meeting of the British Association at Bath (5th).
Opening of the Berlin-Breslau Telephone Line (11th).
Completion of the Electric Lighthouse at the Copenhagen Exhibition.
Opening of the Arc de Triomphe Porte-Maillot Electric Tramway Line in Paris (15th).
Launch of Electric Submarine Torpedo-boat "Gymnote" at Toulon (25th).
Threatened Strike amongst Paris Telegraphists.
The Society of Arts Motor Trials.
Formation of an Electrical Institute in New South Wales.
Report of the new Directors of the Maxim-Weston Company.

OCTOBER.

Experiments at Issy with an electric submarine torpedo boat driven by means of a Schanschieff Battery.
Extraordinary General Meeting of the Maxim-Weston Company (3rd); the late chairman to be proceeded against.
Unveiling of a Statue to Ampère at Lyons.
The Town Clerk of Swansea directed to apply to the Board of Trade for a Provisional Order to light the town by electricity.
Blenheim Palace lighted by electricity.
Death of M. Cabanellas.
Opening of the new Burg Theatre at Vienna (14th inst.); lit by over 5,000 incandescent lamps.
First meeting of the Electrical and Allied Trades Section of the London Chamber of Commerce (22nd inst.).
The Town Clerk of Dublin instructed to take the necessary steps for procuring a Provisional Order (22nd inst).
Visit of the Technical Press to the Deptford Central Lighting Station of the London Electric Supply Company (24th).
Foundation stone of the Bradford Station laid (26th).
Inaugural *conversazione* of the Institute of Medical Electricity (30th Oct.).
Important agreement between the Westinghouse, Sawyer-Man, and Consolidated Companies of the United States.

NOVEMBER.

Visit of Kensington Vestry to Eastbourne Central Station (5th).
Report of the Manchester Jubilee Exhibition issued; total number of arc lamps employed, 512; total number of incandescent lamps employed, 3,570.
Trial of the Julien Car at Birmingham (7th).
Publication of the Brussels Exhibition Awards.
Tenders for the lighting of the Halles Centrales (Paris) sent in.
Electricity Applied to Tanning at Nordköping, Sweden.
Society of Telegraph-Engineers and Electricians resolve to change the title to that of the Institution of Electrical Engineers (8th).
Large Contract given by the Metropolitan Electric Supply Company to the Westinghouse Company.
United States Supreme Court reverses decision of Lower Court, and holds that the Government can bring suit to invalidate the Bell Telephone Patent (12th).
Meeting of the Pacific Cable Conference (21st).
The Thomson-Houston Electric Company commence an Electric Railway, 14 miles long, at Topeka (Kansas).
The Directors of the Pilsen-Joel Company recommended to wind up the Company (23rd).
Death of M. Lucien Gaulard (26th).
The case of King, Brown and Co. *v.* The Anglo-American Brush Corporation came before Court of Session in Edinburgh (27th).
Trial of a 125 horse-power Daft electric locomotive on the New York Elevated Railways (27th).
Messrs. Siemens and Halske secure the contract for lighting the Vienna Houses of Parliament.

DECEMBER.

Rejection of the memorial of the Chelsea Electricity Supply Company by the Chelsea Vestry, which resolved to allow the Cadogan Company and the London Electric Supply Corporation to lay underground wires in the neighbourhood.
Swan-Edison *v.* Holland and others. Appeal against Mr. Justice Kay's judgment (1st).
Maxim-Weston Company. The shareholders agree to the voluntary winding up and reconstruction of the Company.
Publication of the Programme of the International Congress of Electricians.
Acceptance of Messrs. Nicholson and Jennings's tender for the lighting of Cowpen (5th).
The Dublin Corporation reject the vote for the preliminary expenses connected with the electric lighting scheme (5th).
Inauguration of the Ipswich Central Station, constructed by Messrs. Lawrence, Paris, and Scott.
Sir William Thomson elected President of the Society of Telegraph-Engineers for the year 1889 (13th).
Experiments at Mr. Edison's laboratory with regard to the effect of currents of electricity on animal organisms.
Bath Urban Sanitary Authority affix their seal to contract with Mr. Massingham for the lighting of certain streets by electricity.
Prolongation of the agreement with the Submarine Telegraph Company until March 31st, 1889.
Royal Assent given to Patents, Designs, and Trade Marks Bill (24th).
The Board of Trade decide not to issue any further licenses for the Metropolitan area.

UNITED RIVER PLATE TELEPHONE COMPANY.—The directors of this company have declared an interim dividend for the half-year ended 30th September last of 3 per cent. (being 3s. per share), free of income-tax, payable on and after the 15th inst.

THE BOARD OF TRADE AND THE LIGHTING OF LONDON.

The following is a copy of the text of the memorandum recently addressed by the Board of Trade to the London Electric Supply Corporation and the Metropolitan Electric Supply Company:—

[Copy.]

"Board of Trade, Railway Department,
"London, S.W., November 23, 1888.

"Gentlemen: I am directed by the Board of Trade to state that they have had before them the application of [your] company for a license under the provisions of the Electric Light Acts, 1882 and 1888, in respect of an area comprising an extensive part of the metropolis. After a careful consideration of the application, the Board of Trade are of opinion that there are grave objections to the grant of a license for so large an area of the Metropolis, one of the most prominent of these objections being that no opportunity is afforded to Parliament to review the decision of the Board of Trade. In a matter affecting so many interests and such a large portion of the population of London, it is not in the view of the Board of Trade expedient that their action should be entirely without direct parliamentary sanction, such as is given when the procedure is by Provisional Order.

"In these circumstances the Board of Trade have come to the conclusion that they cannot properly proceed with the application referred to.—I am, gentlemen, your obedient servant,

(Signed) "COURTENAY BOYLE."

DYNAMO REGULATION BY MEANS OF A THIRD BRUSH.*

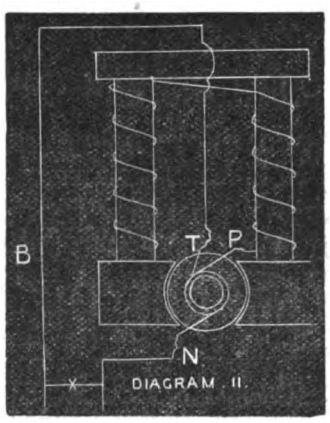
BY EDWARD CALDWELL, A.B., M.E.

(Concluded from page 219.)

The requirements for constant potential regulation are radically different from those necessary for constant current. Recurring again to Prof. S. P. Thompson's fundamental equation of the dynamo,

$$E = 4\,n\,A\,H,$$

where n and A are both constant, it is evident that if E is to be a constant H must also be a constant. Hence, for constant potential regulation the exciting current of the field coils must be a constant.



It is believed that the method here described for obtaining this result has not before been applied for this purpose. The arrangement is a very simple one, as shown in Diagram II. The third brush line passes through a low resistance, and is joined to the main line at the positive terminal of the machine, just outside the field-coils. In this case either no resistance or a very low one is placed between the third and positive brushes, and no automatic arrangement is necessary, as the point of junction is a fixed one. Diagram III. shows the connections as used in the experimental work.

The effect of using different resistances in the third brush line is shown by Tables 15 to 19, and curves 1 to 5, Plate C, plotted from these tables. The third brush remained fixed at 36deg. in advance of the positive brush, this being given as before, 12deg. lead. Curve 6 of the same plate is plotted from Table 20, and is the characteristic of the machine run as a series dynamo, reduced to the same speed as Tables 15 to 19.

* Revised abstract of graduating thesis, Sibley College, Cornell University, June, 1888. Reprinted from the New York *Electrical Engineer*.

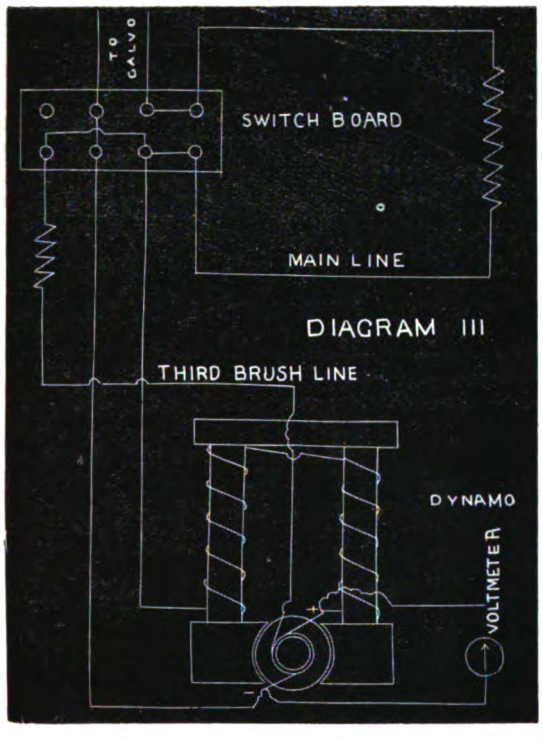
Curves 7 to 11 of Plate D are plotted from Tables 15 to 19 with external resistances as abscissæ, and current in the third brush line as ordinates, and correspond respectively to curves 1 to 5. Plate C Negative current is plotted below the axis of X and positive current above.

These curves and tables show: (1) that the current in the third brush line is, at first, with high external resistances, negative, having its highest value when the external resistance is infinite or when the main line circuit is open; that with decreasing external resistances it gradually decreases, passes through zero, and again rises in the opposite direction; (2) that the point at which the third brush current becomes zero is independent of the resistance in the third brush line, becoming zero in each curve at exactly the same external resistance, and that this zero point is the point at which the new curve crosses the series characteristic; (3) that increase of resistance in the third brush line reduces the regulating power of the third brush, the curve at the limit coinciding with curve 6; (4) that increase of resistance in the third brush line decreases the field current, and consequently the E.M.F., but that the external current is practically independent of the resistance in the third brush line;

Digitized by Google

(5) that the most constant E.M.F. is produced when the third brush line has a resistance of about three ohms—in this case about twice that of the field coils. This resistance, however, will vary, not only with the resistance of the field coils, but also with the angular advance given to the third brush, and with the amount of current necessary to produce saturation—that is, with the quality and quantity of iron in the cores.

The explanation of these phenomena is slightly different from that already given for the changes observed in the case of constant current regulation. The same equation, however, is applicable. Using the same symbols as before, equilibrium will exist between the ends of the third brush line, when $E_d = E_i$, or $C'R' = 4\pi H'A'$. In this arrangement R', which is here the resistance of the field coils only, remains a constant. A decrease of A' by bringing the third and positive brushes nearer each other, or, within certain limits, an increase of C', will make $E_d > E_i$ and make the third brush positive. If now A' remains constant and C' be increased by a decrease of the external resistance, H' will increase in direct proportion as long as the iron of the field-magnets is in the unsaturated condition, and there will be no change in the value of the equation, $E_d = E_i$. But as soon as the saturation point is reached, H' becomes practically a constant, and further increase of C' will make $E_d > E_i$ and the third brush positive. In Tables 15 to 19 the field-magnets are fully saturated when $E_d = E_i$, and hence *any* increase of C' makes $E_d > E_i$. Had A' been much smaller this result would not have been obtained.



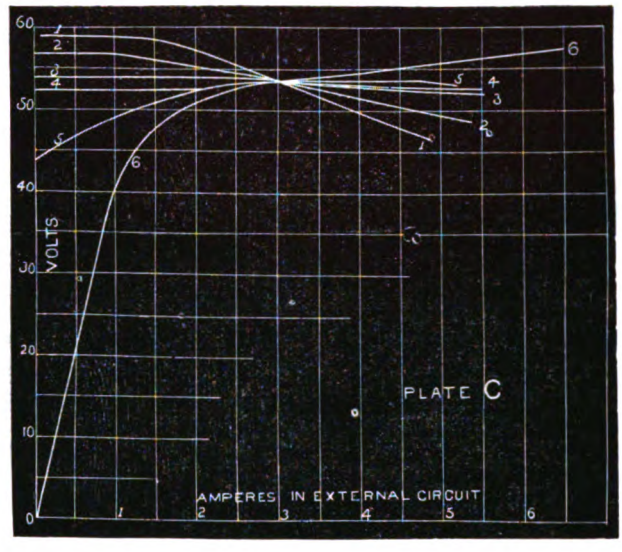
The two opposite changes will make $E_d < E_i$ and the third brush negative, viz., an increase of A', or a decrease of C'. A decrease of C', however, will produce this result only when, as before, the iron is fully saturated. This is shown in the first part of Table 19, where the field current was not sufficient to produce saturation of the magnets, and, as a result, the current in the third brush line remains practically unchanged, while C' undergoes considerable variation.

It is evident that the potential of the two extremities of the third brush line is independent of the resistance of the line, and hence any variation in this resistance will have no effect upon the point at which its two ends will be at equal potential. It does, however, determine the amount of current flowing in this line, and hence the amount flowing in the field coils; since when the third brush is negative it adds its current to that of the field coils, and when it is positive the current in it is shunted *from* the field coils, as in the constant current regulation. This resistance must be low enough to allow of complete saturation of the field-magnets.

Here, again, we have an arrangement which is in reality equivalent to a compound-wound dynamo. Referring to Diagram II. and the first line of Table 17, it will be seen that the field coils perform the part of series coils in carrying ·6 of an ampere from the positive brush P around the external circuit to N, and at the same time, as shunt coils, carry 1·63 ampere from P around the field-magnets to T, the third brush. The same three types of dynamos are here brought into use, viz.:—

1. Series dynamo + cumulative shunt coils.
2. Plain series dynamo.
3. Series dynamo + "differential shunt" coils, and the conditions under which each is brought into use are precisely like those already met with in regulation for constant current.

As was pointed out in the discussion of the constant current regulation, the application of the third brush necessarily interferes with the symmetrical flow of current in the armature, those coils lying between the third and positive brushes carrying more or less than the other coils, according as the third brush is negative or positive. In properly constructed dynamos this should produce no detrimental effect. It should, however, be taken into account in dynamo design when computing the size of armature wire from the amount of current it is to carry, for it is evident that in this case one-half the total current in the external circuit is not the maximum current which the armature coils must carry. A similar remark applies to the size of wire for the field coils.



A decrease of the resistance of the field coils would decrease the loss of potential between the positive brush P (Diagram II.) and the point B, and, the potential of T remaining constant, would increase the negative current in B T, and, other things being the same, the lower the resistance of the field the lower the resistance of the external circuit must be made before B and T are brought to the same potential, or, in other words, before the new characteristic crosses the series characteristic; and if this point is not

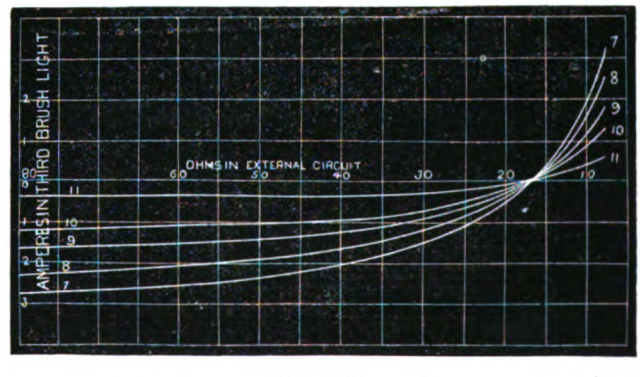


PLATE D.

reached within the limits of the machine only the first of the three types of dynamos mentioned above is made use of. The same effect is produced by giving increased advance to the third brush, thus lowering its potential. Increased resistance of the field or decreased advance of the third brush will produce opposite effects. It will be found that whatever the field resistance or the advance of the third brush, there will be a corresponding resistance for the third brush line (and this in conjunction with the field coils may be regarded as the shunt circuit of a compound dynamo), for which the machine will produce a constant E.M.F.

Prof. S. P. Thompson has observed that the efficiency of any compound-wound dynamo for constant E.M.F. is very nearly a constant. Using his equation for efficiency, this is very nearly obtained from Table 19 and curve 5, Plate C, and this is probably very near the true curve for constant E.M.F. at the *terminals* of

Digitized by Google

the machine, the volts here being the difference of potential between the brushes.

It is hoped that at some future time an experimental study, similar to that described above, may be made of third brush regulation for electric motors for both constant current and constant potential circuits. The field is an inviting one, and cannot fail to be productive of useful and practical results.*.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *December 22nd*, 1888.

The Western Union Telegraph Company has just issued its statement of business for the quarter ending the year. Owing to the unusual amount of work done at the time of the presidential election there is a notable increase, and the net revenue is set down at $1,650,000, being an increase of $150,000 over the corresponding period of 1887. It also appears that the net revenue for the quarter ended September 30th is $157,000 above the estimate made three months ago, so that altogether the company is in good shape. The earnings are at the rate of over 7 per cent. per annum, but the old rate of 1¼ per quarter has been declared.

The American Bell Telephone Company has also just declared its regular quarterly dividend of 3 per cent. It is understood that the company is earning at the rate of 24 per cent. per annum, but the stockholders seem fairly well satisfied if they can draw, as they do, with the "bonus" a modest 16 or 18 per cent. on their investment.

As many of your readers have doubtless learned by actual observation, our lakes that border the northern frontier are big inland seas. Even if they have not seen them, they have perhaps formed some idea of their magnitude from the ordinary figures that are published; but unless one actually sees it little idea can be formed of the vast commerce which has grown up along the shores of the lakes, and which commands the services of hundreds of large sailing vessels and steamers. The great lakes have their storms, well nigh equalling those of the mid-Atlantic, and they have also a lighthouse department as important as that which guards our coasts. The first of the lake lighthouses in which the electric light has been placed is that which has just been put up at Chicago, which is not less busy a port than it is a railroad centre. This new lighthouse is near the North Side pumping station and the new crib of the waterworks. It is a skeleton surmounted by a circular glass lantern, which carries twenty-four 32 candle-power lamps, mounted in a circular silver glass reflector, which throws a beam for eight miles. An interesting feature of the work is that the current is conveyed out to the lighthouse by five lead-covered cables laid in a tunnel, and another interesting feature is that the current is used for sounding fog alarms; in other words, a small motor has been put in, which strikes a fog bell of 600lb. weight suspended in the lantern. This bell is struck by a 20lb. hammer, which is raised and dropped eight times a minute by a revolving cam. The motor is securely bolted underneath the floor of the lantern, and is under control distinct from that of the lamps. The service given and the results obtained appear to be very satisfactory.

While on the subject of marine motors I may as well make note of the sensation which is being caused here by the publication in one of our weekly journals of a weekly novel by Mr. Frank R. Stockton, entitled "The Great War Syndicate." The idea of the story is that at the close of the present century, in spite of the work recently done by Mr. Joseph Chamberlain, war breaks out between the United States and Great Britain and Canada over the Fisheries. The outbreak of hostilities comes like a thunderbolt, and finds the country, though highly prosperous, thoroughly unprepared for the emergency; while England is represented as being ready with any number of fine ironclads, Lord Randolph Churchill to the contrary notwithstanding. The swift British cruisers chase and capture American merchantmen, and the angry enthusiasm of our people runs high, while the Government becomes daily more anxious and despondent. At this juncture a number of our leading wealthy men meet together and form a syndicate, make a contract with the Government, and take off the hands of the little army and navy the job of fighting the fleets and troops of England. This will strike you as an essentially American way of looking at things; but, after all, as the bankers generally carry on the big wars, there may be nothing extremely original about it, so far as raising the money is concerned. But this war syndicate not only supplies the money for the work, but the energy and the brains. It gets hold of some important inventions, and launches a fleet composed of two peculiar classes of ships. In these ships, which are called respectively "repellers" and "crabs," electricity has the star *rôle*. The repellers are provided with gigantic guns, operated by electric motors and projecting instantaneous motor bombs which wipe out everything they strike, from a ship to a city. The crabs are monitor-like craft, also provided with "electric engines," which operate long nippers. The object of these nippers is to seize the rudder gear and screw-shaft of every ship of the enemy, and in this manner to disable them and render them an easy prey. According to Mr. Stockton's story, a small fleet of these extraordinary craft blockaded a Canadian port, and there not only shaved big forts clean off the face of the earth, but shattered and bore away the rudders and screws of the ships of the defending men-of-war, putting them in such a condition that they were utterly unfit for service. The story goes on to describe how the British Admiralty equipped as quickly as possible its new ships and met this new style of warfare; but no great success attended their efforts, and the first part of the story leaves the syndicate practically master of the seas. There is some clever work in Mr. Stockton's fiction, and although it is very incomplete and absurd in some of its details, it has set the public thinking, not only of the insecure state of our coast defences, but as to what the navies of the future are likely to be, with all the improvements that electricity is now furnishing them. It will be seen that Mr. Stockton is working on the lines of Jules Verne, adding to popular science a marked dash of what is known as "American humour."

One of the leading sensations this week has been the publication in some of the daily papers of negotiations that have generally been known to be in progress very quietly for a reorganisation and consolidation of all the big Edison interests in this country. It is understood that the conduct of the negotiations has been in the hands of Mr. E. H. Johnson, the energetic president of the Edison Company, and Mr. Henry Villard, a very able financier, at one time prominent in connection with the Northern Pacific Railroad, and to-day one of the magnates of Wall Street. As you are probably aware, most of the actual work of supplying material for the Edison system has been done by subordinate manufacturing concerns, which have made handsome earnings and profits; and the proposition now is to bring all the interests together under one management, and issue stock to cover the whole. It is said that the new stock will be £2,500,000, and that in view of the contemplated change the present Edison Stock has already gone up to 170. From the way the papers talk it might be inferred that a scheme is afoot to consolidate all the electric light interests of the country, but there seems no reason whatever for the suggestion.

Speaking of Edison matters reminds me that Mr. W. J. Jenks, director of the Edison Standardising Bureau, read a Paper before the American Institute of Electrical Engineers this week on "Six Years' Experience with the Edison Chemical Meter." The Paper drew a large audience, and was well received. It contained an abundance of data, both scientific and practical, the latter predominating, and was freely illustrated by lantern. Mr. Jenks adduced conclusive evidence in support of the superiority of a meter system for selling current, as compared with a flat rate or contract basis; and he was not less successful in proving that the Edison meter had been an efficient piece of apparatus for its purpose. He stated, however, that it was intended to introduce a number of improve-

ments, and outlined them. The illustrative part of the Paper was made the more interesting by the inclusion of a number of views from patent and other drawings, showing the evolution of the Edison Chemical Meter, and the ingenious efforts made by Mr. Edison to utilise sundry principles in bygone years. Altogether the Paper is a highly valuable addition to the fund of information on the meter subject.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *December 26th*, 1888.

At the meeting of the Conseil Municipal which took place on Saturday night last, permission to lay cables in the streets for the distribution of electric current from central stations was, after a long discussion, granted to the following companies:—The Compagnie Continentale Edison; the Compagnie Parisienne (Victor Popp); the Société Anonyme pour le Transport de la Force par l'Électricité (Marcel Deprez); the Société d'Eclairage Electrique du secteur de la Place Clichy (A. Koechlin and Georges Fournier); the Parisienne Electrique, &c. (M. Censier, Electrical Engineer.) The ground covered by these authorisations is entirely on the right side of the river, and comprises nearly half Paris, from the Bois de Boulogne on one side, to the Quai de Bercy on the other. I have been told that permission has been asked for a district on the left side of the river, but the demand was not discussed on Saturday last. Looking at a map of Paris, one is astonished at the area already asked for. One must also not lose sight of the fact that the authorisations have been granted under a security of 300,000fr. in each case, and under an agreement to have cables laid in all the large streets within two years, and within four years in every street where 10 lamps are asked for per every 10 metres.

Although the decision of the committee for the electrical lighting of the Halles Centrales has not been yet officially announced, I can still give you the names of some contractors whose tenders have been accepted:—Belleville and Company, for boilers; Weyher and Richemond, and Lecoulteux and Garnier, for steam engines; the Edison Company for the low-tension currents, and the Ferranti system for the transformers. Nothing has been decided up to now as to the lighting of the pavilions of the Halles with arc lamps, but it is probable that the preference will be given to the Thomson-Houston system.

The number of private installations in this city is increasing rapidly, and some of them are rather important, such as the underground floor of the Crédit Lyonnais, with 300 lamps; the Conservatoire Naticnal de Musique, with 390; the Society of Civil Engineers, with 100; the Piscine Rochechouart, with 45 Thomson-Houston arc lights; the Bouillons Duval, the Bouillons Parisiens, the show rooms of the Choubersky Company, and many others.

In a few days the station at the Palais Royal will commence operations. It will start with 2,000 incandescent lamps, but this number will rapidly increase as more plant is installed. The machinery will consist of eight Belleville boilers and eight Weyher and Richemond vertical steam engines, running at 130 revolutions a minute, everyone of them being directly connected with an Edison dynamo of 800 amperes and 110 volts, running at the same speed.

In the provinces the municipalities and inhabitants regard the electric light with more favour than ever; Nimes, Troyes, Perigueux, Grenoble, Avignon, and many other smaller towns are studying the means of distributing electric current for public and private use, and there is no doubt that this tendency will greatly increase after the favourable vote of the Parisian Conseil Municipal.

Most of your readers will no doubt have seen a good deal of late in the papers about M. Zédé's new submarine boat, the "Gymnote." At a recent meeting of the Académie des Sciences Admiral Paris read a short Paper on this interesting subject, and in the course of his remarks showed himself very enthusiastic in this matter. Amongst other things Admiral Paris said: "In short, we are able to say that the 'Gymnote' moves and steers equally well above or below the water, that it can be kept accurately at the desired depth, that its speed is all one could expect, that respiration is unimpeded, and that it is easy to see, down to a certain depth. M. Zédé says that Captain Kreb's electric motors are marvels of lightness and precision, and that this important part of the boat has been carried out in a most masterly manner. The energy available amounts to 240 horse-power-hours. So complete a success would have been impossible without the scientific ingenuity and minute care which M. Romazoff, naval engineer, of Toulon, brought to bear upon every detail. Here, then, we have a solution of the submarine-boat problem. The first step has been taken; better work will be done in the future. But even as it is the 'Gymnote' is capable of rendering good service."

NOTES FROM BRUSSELS.

(FROM OUR CORRESPONDENT.)

BRUSSELS, *December 29th*, 1888.

A syndicate of electricians which has recently been formed has offered to assist the Brussels authorities in their deliberations upon the central lighting station question. The syndicate made its proposal in the following terms:—"We learn that the city of Brussels is seriously studying the question of central stations for the distribution of electricity for light and power purposes. This question is of such vital importance to the town as a manufacturer of gas, and to the general welfare of the inhabitants, that we offer our assistance without hesitation. With this object in view some of us are willing to hold ourselves at your service in order to elaborate a well-considered plan in concert with any delegate you may think fit to appoint. On the other hand, we think that the national interests which we represent are worthy of your consideration; in fact, being all of us producers, and employing in our workshops at Brussels a large number of hands, for whom we have created a new and prosperous trade, we greet the projected central stations as a means of employment to a still larger number of workmen, and as affording a new outlet to the labouring classes of Brussels." The municipal authorities really do seem to be bestirring themselves with regard to the electric light. For some time past it has been proclaimed that the day was at hand when electricity would prove a serious rival to gas, and a menace to the revenue drawn by the town from its gasworks. The time which has so long been announced as at hand seems now to have actually come. The town of Dolhain, for instance, in the Province of Lemburg, is at the present moment lighted by electricity, and everyone is satisfied, the consumers as well as the Communal Treasury. Our local authorities are awake at last; better late than never. But to return to the syndicate. It is composed of the five principal electrical firms in Brussels, and taking into consideration the variety of systems advocated by the several members, it is tolerably safe to predict that it will meet with no greater success than its predecessor. It will, perhaps, be within the recollection of your readers that a previous attempt to form a syndicate came to an untimely end when the contract for the lighting of the Gare du Nord was put up to tender, which shows that there are no real means of reconciling conflicting interests, which invariably lead to disunion at the critical moment. Although the composition of the syndicate has been somewhat altered, the facts are still the same; the same divergent interests are there, and it appears to me as if the only *raison d'être* of the new combination was to allow the several adherents to keep closer watch over each other. One factor ought certainly not to be lost sight of by the syndicate, namely, that the city authorities, as in the case of gas, will certainly run the central stations themselves, so that the only profit to be looked for by outsiders will be that arising from the sale of material. It appears to me, therefore, that the syndicate is in a position somewhat similar to the gentleman who offered a bear's skin for sale before he had shot the bear. Moreover, the syndicate is certainly no promoter of national industry, comprising, as it does to a large extent, representatives of foreign firms whose wares have already flooded our market, and which generally defy home competition by their cheapness, and, I may add, by reason of the favourable support accorded to them in high quarters. The authorities will not lack advisers, and will come to their final conclusion with a full knowledge of the facts. I think it, however, advisable to place this matter, as far as the syndicate is concerned, upon its true basis, and to show what would inevitably be the result of the success of these five firms, who are anxious to divide the lighting of all Belgium between them.

An installation has just been started at Ghent which may prove of great importance to the maritime trade of this town. For some nights the light of several large arc lamps has rendered the night-work on the quays as expeditious as that carried on during the day. The regular service will not begin before the 1st January, from which date the town authorities will furnish the light to the ships using the dock. Formerly the steamers arriving at this port, if they wished to unload without delay, were obliged to do so as best they could by the light of petroleum lamps or gas lamps; now the work can be carried on as easily by night as by day, and the advantages arising from these facilities cannot be overrated. Here are a few details concerning the installation. The engine and dynamo are placed in the room containing the hydraulic machinery connected with the dock cranes, the engine being a Parsons steam turbine running at 10,000 revolutions a minute. The lighting is done by eight 1,200 candle-power Dulait arc lamps, placed on iron masts 10 metres high. In addition to the arc lamps there are several portable incandescent lamps enclosed in lanterns, which are of great use in lighting up the holds of the ships. The installation was carried out with great rapidity, for the work was only begun on Thursday, 6th December, and the lights were running on

Digitized by Google

the following Tuesday. The system adopted is that of M. J. Dulait, director of the Société Électricité et Hydraulique de Charleroi. This company, I may mention, is very busy at present with other installations in East Flanders, and has successfully competed in several instances with one of the foreign companies which have their head-quarters at Brussels.

M. Cordenraus, the manager of the Central Hotel, has decided to light his splendid building facing the Bourse by electricity; the installation will comprise 15 arcs, and from 200 to 300 incandescents. The question of motive power has not as yet been definitely decided, but I hear that gas engines will most probably be used, owing to the difficulty of obtaining the requisite permission for the erection of boilers and steam-engines. The arcs will be used on the balconies and in the courts and halls, the incandescents being confined to the café, dining room, bed rooms, and cellars.

The announcement of the Exhibition awards has been followed by a short report on the electric lighting arrangements. With wise prevision the promoters of the Exhibition called upon every system to compete for the lighting of the buildings and grounds, no system being excluded *à priori*. The result of this was to give the public an unequalled opportunity of seeing the various methods of lighting running side by side, and to show them that, even where the force of circumstances necessitates rapid work, no danger need be feared if only the matter is entrusted to competent persons. In your country and in America the high-tension system has gained great favour, combining as it does the two *desiderata* of modern industry, economy and rapidity. With us, however, the case is different; the public is not so familiar with the sight and use of machinery, consequently the idea of high-tension currents is not liked, and low-tension systems are more in harmony both with public opinion and with the law. Another reason for the preference which is accorded on the Continent to low-tension systems is the inexperience of the workmen. We have got into a groove in this respect, and although we have no doubt made the system as perfect as it can be made, nothing can compensate for its expensive and cumbersome character. Now, in my opinion, one of the chief claims which the promoters and organisers of this large scheme of electric lighting at the Brussels Exhibition have to our gratitude, is that they clearly demonstrated the harmless nature of any properly erected electrical installation. A dozen unknown systems were run in close proximity to one another, and yet not a single accident occurred, a result which reflects great credit on M. Bandsept, who was in charge of the running of the wires as well as of the working of the whole electric light installation.

MM. Mourlon Frères have just formed themselves into a company under the title of Compagnie de Télégraphe et de Téléphonie Internationale. The new company will be under the management of M. Ch. Mourlon, M. Van Rysselberghe being the consulting engineer. Besides its telephonic and telegraph business, the new company intends to go in for electric lighting by means of batteries or dynamos, and it will also turn its attention to the sale of phosphor-bronze wire.

The *Etoile Belge* has just scored a point in the race for early news. On Friday last it published in its second edition at 10 a.m. full details of Prado's execution, which appeared in the French papers some fifteen hours' later. This unusual rapidity was due to the special telephone service of the *Etoile Belge*.

I noticed on MM. Mourlon's stall at the recent Exhibition an ingenious arrangement for checking the movements of night watchmen. It consisted of a long drum, driven by clockwork, and covered by a roll of paper. Close to the drum there were just as many electro-magnets as there were signalling points. Each of these electro-magnets was armed with a small punch, and whenever the button at the signalling point was pressed the paper on the roller was punched, and by means of the divisions on the paper it was possible to tell within a minute or two when the signal was transmitted. Any tampering with the wires or apparatus caused an alarm bell to ring.

CORRESPONDENCE.

ELECTRICAL DISSIPATION OF FOG.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The remarks made in your editorial last week (page 213) on the inertness of people in attempting to dissipate fog by discharging electricity into it are well justified, and one of the persons most inert in the matter has been myself. I have been thinking of making the attempt ever since the Montreal meeting of the British Association, but hitherto I have been deterred, principally by the initial expense. Your surmise that the whole thing could probably be done for £10 by no means agrees with my estimate. In practice I find that hardly anything can be done for £10; and for a trial on any reasonable scale I estimate that something more like £1,000 is necessary.

A good many preliminary experiments appear to me necessary before one can decide what is the best way of getting the electricity up. A Wimshurst machine is all very well, but the quantity it is able to supply would hardly be likely to make much impression on the atmosphere at large. I am by no means sure but that a battery of an enormous number of cells would not be a more likely plan.

However, I have gone so far as this: I applied some month or two ago to the trustees of the "Elizabeth Thomson Science Fund" in America for £100, to cover part of the cost of a room and assistant and power and a large Wimshurst machine, with which to make some preliminary trials. The result of this application is not yet known.

As soon as I am able to adduce evidence of a reasonable prospect of success I propose to move for a committee of the British Association, or, better, of the Royal Society, to act as a recipient and trustee of some considerable sums to be expended on really large-scale operations. I apprehend that there would be little difficulty in obtaining funds for the purpose if one could hold out a distinct prospect of success. But at present my experience is confined to the clearing of a smoke-filled room; and though the ease with which this is done raises one's hopes as to what can be done in a stagnant atmosphere, yet, considering the enormous space to be affected, and the multiplicity of points which may act as dischargers, unless the supply is taken to a considerable height, I have not liked to bring the matter prominently forward, either before my own friends here in Liverpool or before the public at large. I hope, however, to be able to do so with a good conscience before the arrival of 1890.

OLIVER J. LODGE.

University College, Liverpool, 1st Jan., 1889.

[In mentioning an expenditure of only £10 we had in view merely a preliminary experiment, chiefly in order to determine whether a mixture of aqueous vapour and soot is at all tractable to electrical treatment. Everyone will, however, be pleased to hear that Dr. Lodge by no means despairs of success. In the dense fog of the last night of the old year it is said that in some of the London theatres the stage was scarcely visible from the back of the house; so that even if out-door operations are unsuccessful, there would still remain a limited, but still a very useful, field for its utilisation.—ED. *E.*]

ELECTRO-MAGNETIC SHUNTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: M. Godfroy, in the *Comptes Rendus* for November, 1888, has suggested the use of an electro-magnetic leak, possessing considerable self-induction and fixed at the entry of the wire into each station, to improve the speed of working through long wires. I think if he were to experiment a little more he would find that it would have a very small effect compared with the effect of a shunted condenser such as we use in the Post Office service. I experimented with leaks, electromagnetic and otherwise, some years ago both for automatic and telephone working, and I found that simple resistance leaks had a more beneficial effect upon rate of working than electromagnetic ones. The following experiment is instructive:—

R—Resistance of circuit	1,782ω	
K—Capacity of „	54 mfd.	
K R	96,228	
E.M.F.	100 volts.	
Speed by calculation ..... $\left\{\frac{10,000,000}{K R}\right\}$	104	words per min.
„ without leak (actual)	107	„
„ with 100ω leak (plain)	130	„
„ with 570ω „ „	125	„
„ with 570ω (electromagnetic)	125	„
„ with shunted condenser	177	„

($r = 8,000\omega$, $K = 2{\cdot}75$ mfd.)

—Yours, &c., W. H. PREECE.

G.P.O., January 2, 1889.

FLASHED FILAMENTS IN LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Has anyone observed that the result of the so-called flashing process is necessarily to produce a conductor which tapers to the ends? Wherever the temperature of the surface is hottest, for any cause, there a more rapid deposition of carbon will take place; and where the temperature is lower a less rapid deposition will occur. Now, consider a simple arched conductor, which we will suppose to be of initially equal section from end to end. When rendered incandescent, the end portions, being connected to non-incandescent mountings, will be cooled by them. Those parts which are subjected to the end-cooling will necessarily be at a lower temperature, and will therefore receive a less thick deposit of carbon. Again, in the case of conductors which are bent, not merely into an arch, but into a loop of one or more turns. Those portions of the conductor which lie near to one another will radiate to one another, instead of merely radiating out to cooler objects. They will consequently help to raise one another's temperature. Were the conductor, then, initially a wire of perfectly uniform section, those parts which are thus mutually heated will tend to receive a thicker coating of deposited carbon than the straight limbs leading to the mounts.

In every case the result of flashing will be to so build up the size of the conductor that every part shall glow with equal radiance, in spite of its accidental position, whether subjected to a cooling effect or to a heating effect from the adjacent portions of the lamp. Flashing will not, as often alleged, reduce all portions of the conductor to equal size or equal resistance per unit of length, and it weakens the conductor mechanically by leaving it thinner near its mountings.

The existence of this tapering structure can be actually observed by the eye in some flashed lamps, and is capable of measurement by a micrometer gauge.

The following measurements were made by the writer upon a flashed 105-volt "Victoria" lamp. Measurements bracketed together were made at the same point in two diameters approximately at right angles to one another:—

	Diameter in millimetres.		
At bow of loop	·145, ·150	mean	·1475
Half-way down limbs	·150, ·140		
" " "	·135, ·150	"	·1437
At end, near mount	·095, ·105		
" " "	·110, ·105		
At other end, near mount	·090, ·100	"	·1012
" " " "	·105, ·100		

In another similar lamp the mean diameter of bow and limbs of the arch was ·130 millimetre, and that of the ends close to the mount ·100.—Yours, &c., SILVANUS P. THOMPSON.

20, Arundel-gardens, January 1, 1889.

ELECTRICAL DEFENCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with interest the leader in your issue of November 9th, entitled "Electricity our Defence." If there is a favourable opportunity will you kindly mention the following:—

By implication I am credited with having, in conjunction with General Abbot, assisted in the experiments which led to the adoption of the low-tension primer having the platinum iridium bridge. Much to my regret I have not had the honour of working with the General in this direction, he having completed the experiments long before I commenced the development of the "pneumatic gun."

Whilst of the opinion that we could devise a "range-and-position-finder" capable of doing the work done by that devised by Major Watkins, Royal Artillery, I do not wish to underrate his achievement in the least. I know it to be a *very difficult* problem to solve, and you would oblige me, if opportunity presents itself, to quote just what I said in this respect:—

"I think it possible that some of our own ingenious electricians could produce apparatus quite as efficient as that of Major Watkins. I do not, however, wish to be understood to belittle the ingenuity or the feat accomplished by Major Watkins. It is a problem not to be lightly approached; but I have sufficient confidence in our own skill to believe that we also could solve the problem."

I send by this mail a corrected copy of my Paper and the discussion, there having been a number of mistakes in the stenographer's notes as previously published in the American press.

I did not state definitely my conclusions as to the use of the electric search light, as I believe it still to be an open question whether it can be used advantageously at all times. The Lucigen, or similar light, if planted at some distance from the works or ship, appears to me to present many advantages over the electric light in not marking definitely the exact position of the defence, and in better showing the approach of attack, when within the zone of the diffused light.—Yours, &c.,

E. L. ZALINSKI,
Captain 5th Artillery, United States Army.

Fort Hamilton, New York Harbour,
December 16th, 1888.

BLONDLOT AND CURIE'S ELECTROMETER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of December 28 you have a note on a modified electrometer devised by Messrs. Blondlot and Curie to give continuous *power* indications on a circuit with a variable current, and thus do away with the two readings required. As far as I can gather from the account the modified electrometer is really a combination of two electrometers acting in combination. The principle of such an arrangement is as follows:—

The usual measurements are made by connecting the quadrant to the ends of the circuit under measurement, and the needle to one end of a non-inductive resistance, the other end of which is connected to the point where the circuit under measurement commences. A second reading is made by connecting the wire from the needle to another point (say half-way) in the non-inductive resistance.

The two readings ϕ and ϕ_1 are then represented by formulæ of the form

$$\phi = V \times (C + K),$$

$$\phi_1 = V \times \left(\frac{C}{2} + K\right),$$

where V a E.M.F. acting on the circuit and C a current flowing in the circuit; whence

$$\phi - \phi_1 = \frac{VC}{2}.$$

Now the deflections ϕ and ϕ_1 are simply the measures of forces acting. Hence, by connecting up two separate electrometers suitably connected with their needles on one suspension, these forces may be added mechanically, instead of by taking separate readings and performing the addition on paper.

This idea is not new, for in 1882, I think, whilst studying under Prof. Ayrton at the Cowper-street Technical School, when he described the method now well known with two readings, I suggested the above method to him, proposing to carry it out by using two separate sets of quadrants and needles suspended by the same thread; and in 1886, in a Paper read by me at a supplemental meeting for students, at the Institute of Civil Engineers, I described the same method.—Yours, &c.,

LLEWELYN B. ATKINSON.

Woodfield-road, Harrow-road, London, Jan. 2, 1889.

[Mr. Atkinson's method seems a good one so far as it goes, but we do not think that he is correct in saying that the principle of the Blondlot instrument is identical; the division of the non-inductive resistance does not occur in the latter method.—ED. *E.*]

ELECTRIC TRACTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I fully appreciate Mr. Reckenzaun's kindly expressions towards me, the which I fully reciprocate towards him personally, and should not have written my slight criticism upon his efforts had the article been signed by himself. Mr. Reckenzaun seems to be labouring under several difficulties, the most prominent of which seem to be getting round or evading the patents held by ourselves and the Electrical Power Storage Company and M. Julien, and persuading the public that he has not only done this but found something better. I have myself seen very similar plates to that he has adopted made by the Electrical Power Storage Company, either in the day of his connection with this company or previously, these plates having been set aside on account of their difficulty and cost of construction. The advantage for the form of plate, viz., the ease with which it may be bent, is practically small, as the plates are not intended to be bent, and must be prevented from this. Were they bent, although the peroxide might not fall from them, the electrical contacts of the oxide with the grids would be much disturbed, and no good would result to the plates, while the plates after this mode of construction must be greatly reduced in active area in comparison with such a grid as I sent with my first letter to your office. I fully appreciate the efforts of Mr. Reckenzaun, having myself from the very earliest period been interested in this question, and although not a prominent actor before the public, I have been constantly engaged, through many channels, in this work.

The exception taken to my statement as to the tendency of cars to leave the road when drawn independently upon each axle on passing sharp curves and points may be warranted, although my experience is to the contrary, and I have found that cars driven by the two axles (the two axles being coupled) have not shown at all similar tendencies. The statement that two motors made of the same weight of material would give an equal efficiency is approximately correct, but the speed of rotation would be very different, and one of the great advantages of the larger motor is in it being possible to reduce the speed, and I have found no difficulty in being able to meet the necessities of space beneath the tramcar with one motor. Respecting the mode of driving, I admit that the quietness obtained by screw-gearing is an advantage, but on seeing this exhaustively tried, the amount of heat generated was so great an inconvenience (although the screw was run in a bath of oil), and the quantity of energy required to do an equal amount of work to the ordinary chain gearing was so excessive, as to condemn it, and this under identical circumstances. I agree with Mr. Reckenzaun that the commercial success of electrical traction does not depend upon a few per cent. more or less in efficiency, but upon the total cost of traction (inclusive of repairs and renewals), and freedom from breakdowns, &c. Mr. Reckenzaun seems to think me personally inclined to evil towards him by denouncing his method of changing the field connections; nevertheless, he states in his reply that the resistances of the fields of his motors are so excessive that he immediately cuts these down to a fourth after starting; yet he objects to using resistance, and then falls below the saturation point of his magnets. These two statements prove the ground for my assertion that this is not an economical mode of using the E.M.F. of the battery; *but it has the merit of being another mode to that of M. Julien.* It has been said that Julien's mode of connecting up batteries is objectionable, which, in practice, I have not found. The only objection to this method is the cost of the switch and its liability to derangement; when used upon tramcars with a suitable motor it effects the best economy of the batteries I have seen or know of. I would welcome public competitive trials of electric cars and any method of making known that which is best for the purpose, and I do not desire for a moment to deprecate the efforts of another; but the long labours of myself and my company in this direction, and the property of my company and the Electrical Power Storage Company in their accumulator patents, the long connection I have had with M. Julien in working at this traction problem, and a strong desire that the investing public shall be thoroughly cognisant of all its merits, rule me in this communication.—Yours, &c.,

T. PARKER.

Wolverhampton, January 1, 1889.

P.S.—In my first letter, *The Electrician*, December 21st, 1888, fourth line from bottom, the word printed "charging" should be *changing*.

ELECTRIC TRACTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As one who has had considerable experience of every kind of the difficulties of initiatory work in electric traction I cordially endorse the concluding observations in Mr. Reckenzaun's letter in *The Electrician* of the 28th December last.

Mr. Reckenzaun says:—"I would rejoice to see other men successfully working——. I think it bad taste to run down in newspapers the work of competitors. We get very little encouragement from the public at large. The prejudices to be overcome are very great, and there is no need of the same being augmented by those most interested in the development of electric tramways."

The subject matter and the full meaning of these observations should be well borne in mind by all who seek, directly and indirectly, to benefit by the general introduction of electrical locomotion. I made similar observations in a letter published in the *Electrical Review* some time ago. There is no doubt that every success, no matter by whom attained, greatly helps all interested. We are on the eve of an enormous development in electrical work from the working of all kinds of vehicles. An immense amount of capital is required in the work to make it move ahead at a satisfactory rate, and the more capital which is successfully employed in the work the better. There is no doubt that with the guarantees which manufacturers are prepared to give for the maintenance of their appliances electric traction has in it enormous economical capabilities, and the time is very close at hand when this will be generally recognised, and the mere economy will force its general adoption on a most rapid scale.—Yours, &c.,

15A, James-street, Haymarket, S.W., RADCLIFFE WARD.
2nd January, 1889.

BATTERY TRANSFORMERS AND THE VIENNA INSTALLATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The theoretical conditions of the battery transformer system inquired into by M. Paul Hoho, and commented on by you in your last number, deserve more careful consideration than has hitherto been given to them. I was greatly disappointed to find no one take special notice of these conditions in the course of the discussions on my Paper last year, so that I now have great pleasure in explaining how the difficulties mentioned by M. Hoho are got over in practice. In the very simple case of the Le Mans installation, where there are only two batteries in series, all that is necessary is to provide a peculiar form of transfer-switch, which at one movement transfers the load from one battery to the other, *i.e.*, after the transfer the battery which was previously giving the heavier discharge now gives the lighter one; but at Vienna, where there are four batteries in series, the matter is not quite so easily arranged. In this case the load is equalised as much as possible by a large plug-board, lining the walls of the distributing switch room. By this means any of the circuits can be switched on to any of the batteries. At Vienna also one or more batteries, if the demand on them is small, can be switched out of the charging circuit, the speed of the engine being automatically reduced in proportion to the decrease of the charging E.M.F. necessary for the reduced number of batteries, by means of Willans' constant-current electric governor. As you truly state, a great deal depends on the watchfulness of the attendant in charge of the switch room in both these cases, and I for some time have been devising means to make the switching arrangement automatic. Every additional month's experience at Vienna only serves to confirm the opinions I have previously formed as to the great value of the battery-transformer system, both in its great economy and in

Digitized by Google

the high sense of security against stoppage of the light which it affords to everyone. I think I am justified in saying that even at the present moment the fuel consumed per net E.H.P. delivered at the lamps contrasts most favourably with any of the direct systems or any of the alternating transformer systems either in England, America, or on the Continent. I am not aware of any difficulties having presented themselves in the working, and the wear and tear of the E.P.S. accumulators has so far not been excessive.—Yours, &c.,

R. E. CROMPTON.

Arc Works, Chelmsford, December 31, 1888.

TECHNICAL EDUCATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: May I ask you to publish and invite criticism on the enclosed Bill, which has been read a first time in the "Kensington Parliament." It is put forward as not antagonistic to, but rather as including (see clause 8) the academic schemes of technical education with which we are familiar. I write as one who was at a primary school, who has worked at the bench, who has great reason to be grateful to the Science and Art Department, who has been a master at a public school, a manager of works, and an employer of labour.—Yours, &c.,

JOHN PERRY, M.E., D.Sc., F.R.S.,

"Vice-President of Council" (Kensington Parliament).

10, Penywern-road, South Kensington, S.W.

[The text of the Bill referred to will be found on another page.—*Ed. E.*]

PRIMARY BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: When I last addressed some observations to you on this subject it was with the object of maintaining that an ideally perfect battery, requiring no more attention than can be given to it by ordinary domestic servants, is peculiarly suitable for supplying electricity in houses of moderate dimensions, where not more than one, two or three electrical horse-power are required for lighting one, two or three dozen lamps. Some further experience has led me to the conclusion that batteries of greater power, capable of lighting groups or blocks of houses from small central stations, would be still more advantageous, for the following reasons:—

1st. Their control and management would no longer be left to the care of unskilled and often unwilling house servants.

2nd. The residual products—the acids as well as the dissolved zinc—would be concentrated in one spot, and in such quantities as to allow of their being collected and converted into valuable commercial products, which is quite possible.

3rd. The current discharged from such batteries is more economically produced, and more easily controlled, than with smaller batteries.

If, in elucidation of this third point, we compare three batteries each of which has an E.M.F. of 1·8 volt per cell, the first producing on short circuit a current of 6, the second a current of 60, and the third a current of 600 amperes, it will be seen that the internal resistance of the small battery will be $\frac{1\cdot8}{6}$, or ·3 ohm per cell, that of the next size $\frac{1\cdot8}{60}$, or ·03 ohm, and that of the largest $\frac{1\cdot8}{600}$, or ·003 ohm per cell. If the battery is composed of 40 cells, the internal resistance of the first will be 12 ohms, that of the second 1·2 ohm, and that of the largest only ·12 ohm.

This internal resistance in the first of the three batteries is equal to $\frac{1}{6}$th, in the second to $\frac{1}{60}$th, and in the third to $\frac{1}{600}$th of the E.M.F. of the battery on open circuit, and whereas the smallest of the three would be almost immediately thrown out of work by any alteration in the strength of the current, the largest of these batteries will have its E.M.F. so slightly affected by an increase or decrease of 10, 15, or 20 amperes, that any alteration may be easily counteracted by automatically switching one or two cells of the battery on or off as the E.M.F. falls or rises.

In other words, the larger the battery is the less will the intensity of the light be affected by alterations in the discharge, or in the number of the lamps required to be lighted by the current; and with the multiple cells there need be no difficulty in supplying current to hundreds or even thousands of lamps from central stations such as I have indicated, which, being noiseless, would be a great convenience in populous districts, as, for example, in the crowded streets of the City.

I believe it is not improbable that at least one such station will be established before very long.—Yours, &c.,

O. C. D. ROSS.

15, Relf-road, East Dulwich, December 24, 1888.

ALLEGED PIRACY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I shall esteem it a favour if you will allow me, through your columns, to enter my protest against the increasing practice of some electrical supply firms of appropriating other people's designs and ideas.

The case I wish more particularly to notice is that of a German firm in London who have just issued a new catalogue and price list, and have included therein, among many other designs, a system of theatre lighting and controlling patented by Mr. E. L. Berry and myself, without even the courtesy of requesting permission to do so, or mentioning whose arrangement it is. I may mention that we have the sole right to determine who shall manufacture and supply these goods.

I feel sure the majority of your readers will agree with me that this is not a legitimate way of soliciting business.—Yours, &c.,

S. SUDWORTH.

6, Estelle-road, Haverstock Hill, N.W., Jan. 2, 1889.

GLASGOW CITY HALL LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: You noticed the official trial of this job in your issue of March 2nd, 1888. I send you a cutting from the *Glasgow Evening Times* of December 24th. For a wonder the critic is quite right. I can endorse all he says, and add more. It is simply painful to sit and watch the exhibition of "How not to do it." Bad carbons I should put down as the cause, from the flaming and sputtering. I have often seen steadier lights from the old Jablochkoff candles, with no pretence at regulation, let alone the old Brush lamp. The lights were bad—very. If the light cannot be improved I, for one, hope to see it out; but the lighting of the Glasgow Exhibition picture galleries was simply splendid by the same system.—Yours, &c.,

G. T. P.

TECHNICAL EDUCATION.

The following "Bill" has been forwarded to us for publication by Prof. Perry, who, as "Vice-President of the Council," has introduced the measure for discussion in the Kensington Parliament. It will be seen by his letter in our Correspondence columns that Prof. Perry invites criticism :—

In the Kensington Parliament, 1888.

A BILL FOR TECHNICAL INDUSTRIAL EDUCATION.

Preamble.

Whereas it is expedient to make provision for technical industrial education in England and Wales. Be it therefore enacted, &c. :—

1. This Bill may be cited as the Technical Education Bill, 1889, and shall not extend to Scotland or Ireland.

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.
The best for overhead Telephone and Telegraph Lines,
AND ALL ELECTRICAL PURPOSES.
Hard Drawn High Conductivity Copper Wire.
ROLLED AND DRAWN
PHOSPHOR BRONZE.
PHOSPHOR BRONZE
BEARINGS, BUSHES,
AND OTHER PARTS OF
ELECTRICAL MACHINERY.
SOLE PROPRIETORS of the British, Indian and Colonial Patents,
THE PHOSPHOR BRONZE COMPANY (Limited),
87, Sumner Street, Southwark, London, S.E.
WIRE AND SHEET MILLS: BAGOT STREET, BIRMINGHAM.

Digitized by Google

2. "Apprentice" means any boy of less than eighteen, or any girl of less than seventeen years of age employed, whether under indentures or not, in any place which, under the Factories or Workshops Acts, is denominated a factory or workshop, or in any warehouse, shop, office, or other place of business, or for wages, or other remuneration, in any place of employment. But apprentice so defined shall not include any menial or domestic servant. "Master" means the employer of any apprentice as hereinbefore defined. "School Authority" means the School Board exercising jurisdiction in the district in which the place of employment is situated, or any elected body which may take over the powers of such School Board; and in places where there is no School Board, it means the county or borough council under the Local Government Act, 1888, or the Municipal Corporations Acts. "Technical education" is an education in the scientific and artistic principles which govern the ordinary operations in any industry. "Technical school" means a place for technical education, whether established and maintained: *a*. By the school authority, and open to all apprentices; *b*. By voluntary effort, and open to the apprentices of more than one master; *c*. Or by a master for his own apprentices. "Inspector" means the inspector of factories in whose district the place of employment is situated, or if there be no such inspector, then the School Board visitor for such district.

3. The Education Department shall forthwith and from time to time prescribe regulations in conformity with the rules for the time being of the Science and Art Department in the subjects in respect of which Parliamentary grants are made by the Science and Art Department, for the formation and instruction of classes of elementary school children who have passed the fourth standard, and thereupon the school authority may form such science and art classes, and provide such instruction accordingly, and earn such grants, and may assign such grants to the teachers of such classes, or may otherwise provide for their remuneration.

4. Every master shall provide each of his apprentices with technica education at a technical school.

5. Every apprentice shall devote at least two hours a day, five days in the week, during working hours, to study at a technical school.

6. The school authority shall annually in January prescribe the time for such study, having regard to the usual working hours in places of employment in their district, and shall publish a table of the times so prescribed. A printed copy of such table shall be conspicuously exhibited by the master in every such place of employment in such positions for such times and in such type and form as the school authority shall prescribe.

7. The school authority shall have power to establish and maintain such technical schools as may be necessary to accommodate and provide technical education for all apprentices in their district whose masters do not otherwise efficiently provide for the technical education of their apprentices. The master of each apprentice shall pay the prescribed fees for his tuition at such schools.

8. The technical schools established and maintained by the school authority may provide technical education for persons other than apprentices.

9. The course of studies at such schools, and fees payable for the same, shall be prescribed from time to time by the school authority, subject to the sanction of the Education Department.

10. The inspector shall inform himself as to the sufficiency of the technical education given to apprentices in his district, and report thereon to the school authority and the Education Department at such times and in such manner as they shall respectively prescribe. The duties, powers, and penalties relating to the office of inspector, specified in the Factory and Workshops Act, 1878, shall be applicable to any inspector under this Act, and to any place of employment within the provisions hereof. The inspectors shall be paid by the school authority such remuneration for their services under this Act as the Education Department shall approve.

11. All offences under this Act shall be prosecuted, and all fines under this Act shall be recovered on summary conviction before a Court of Summary Jurisdiction in manner provided by the Summary Jurisdiction Acts. The provisions of the Factory and Workshops Act, 1878, and the Acts amending the same as to legal proceedings and appeals, shall be deemed to be incorporated in, and made applicable to, this Act. The punishment for any offence under this Act shall be a fine not exceeding £5.

12. The expenses of carrying this Act into execution shall be defrayed by the school authority, who shall have power to provide for such expenditure by moneys raised, precepts issued, or rates levied under their powers. Separate statements of such expenditure shall be furnished annually to the Education Department.

THE EASTERN TELEGRAPH COMPANIES' EAST-END ANNUAL CONCERT AND DINNER.

The seventh annual Christmas Dinner Fund for the poor of the East-End of London, promoted by the staff of the Eastern Telegraph Companies, has this year been a great success. The sum collected amounted to over £120. Amongst the donors were the Lord Mayor, Sir John Pender, K.C.M.G., and Lady Pender, Sir James Anderson, Mr. J. Denison Pender and Mrs. Pender, Miss Pender, Mr. Lewis Wells, Mr. H. Saunders, Hon. A. G. Brodrick, Mr. W. Hibberdine, Mr. G. R. Neilson, Mr. F. E. Hesse, Mr. W. R. Lyne, Mr. J. G. Jack, Mr. E. A. Stuart, &c., &c.

The annual concert, in aid of the fund, was given in the Great Assembly Hall, on December 15th, and added about £40 to the fund. Among the artistes were Messrs. Guildford Dudley, W. J. Finnis, and W. H. Owen, who, as representatives of the Companies, acquitted themselves with remarkable ability. Mr. Arthur Briscoe again officiated at the organ and piano, and to him is due the great success of the musical part of the programme.

The distribution of the dinners took place on Christmas Eve at Mr. Charrington's great Assembly Hall, under the presidency of the Lord Mayor and Lady Mayoress in state. The Lord Mayor, who was most heartily received, gave a very practical speech, commenting on the different causes for the poverty and destitution amongst the masses of the metropolis, at the same time rejoicing that there were such agencies as his friend Mr. Charrington's work for the alleviation of much suffering. Mr. F. N. Charrington proposed a vote of thanks to the Lord Mayor and Lady Mayoress for their presence, which was seconded by Mr. Thos. Richardson, and carried by the thousands assembled with waving of handkerchiefs and much applause.—Mr. E. H. Kerwin, chairman of the Dinner Committee, made a statement showing that 425 families were benefited by the fund, representing some 1,800 persons. The materials for the dinners were then given out, and many a tear of joy was shed at the prospect of once more having a real good old Christmas dinner. The largest families received 7lb. beef, 3 loaves bread, 1½ quartern flour, 2lb. currants, 2lb. raisins, ½lb. suet, ½lb. mixed peel, packet of mixed spice, 2lb. sugar, ½lb. tea, with two oranges by way of dessert, and a small flag with which to decorate the plum pudding. Many a dark, sad East-End home has thus been made bright and cheerful this Christmas by the efforts of the staff of the associated companies.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended December 28th, 1888, amounted to £4,164.

MADRID TELEPHONE COMPANY (SOCIEDAD TELEFONOS DE MADRID). This company announces a distribution of an interim dividend of 10·75 pesetas, or 10 pesetas net. As the shares have 250 pesetas paid up, the distribution is equal to 4 per cent.

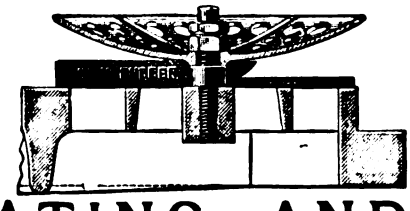
REUTER'S TELEGRAM COMPANY.—The Hon. Mark Francis Napier has accepted the vacant seat on the Board of this company.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended December 28th, 1883 (after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company), were £3,464.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The directors of this company have declared a dividend of 6s. per share for the half year ended December 31st, 1888, payable on the 7th inst.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1888.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

No. 556.—Vol. XXII. FRIDAY, JANUARY 11, 1889. Price 4d.

NOTES.

The important question of electrical standards, and of providing facilities for standardizing instruments in practical use came before the Committee of the Electrical Trade Section of the London Chamber of Commerce on Monday last, when it was decided to request the Council of the Institution of Electrical Engineers to join with them in an endeavour to impress upon the Board of Trade the advisability of Government action in the matter. Our readers will scarcely fail to appreciate both the importance of the subject and the nature of the difficulties with which it is beset. Upon the accuracy or inaccuracy of a voltmeter the popular estimation of the success or failure of an installation to a not inconsiderable degree depends. If the instrument reads too high, people are disappointed with the light provided; if it read too low, they are still more disgusted at the bill for lamp renewals. Moreover, the percentage error which may be allowed without more or less serious consequence is very small indeed—certainly not more than one per cent. on either side. Yet we understand that Dr. Fleming, who has devoted an immense amount of time and trouble to this question, finds that errors of 5 and 6 per cent. are by no means uncommon in instruments ordinarily met with, whilst errors of even 8 per cent. have occasionally come under his notice. We are, however, glad to learn that the experience of testing a very large number of instruments enables Dr. Fleming to state that there has been a very marked improvement both in ammeters and voltmeters during the last two years.

As to the difficulties in the way of a practicable solution, these are chiefly of a financial character. The Committee of the Institution of Electrical Engineers, of which Mr. Preece is chairman, have been able to see their way quite clearly, so far as the technical and commercial details are concerned; but the question is how to meet the initial expense of providing a properly equipped laboratory. It is here that Government aid is sought. An allowance from the Government Grant Committee (from which, for instance, the Kew Observatory is assisted) would have the double advantage of supplying ways and means and placing the undertaking upon a recognised and authoritative basis. The suggestion now is to approach the Board of Trade upon the subject, and if they can be sufficiently impressed with its important bearing upon the public interest it is hoped that no great delay need occur before this much-needed reform is carried out. We may add that it is believed that the establishment would soon become self-supporting, the current cost being defrayed by the charges for re-calibration.

Another reform of almost equal importance with the foregoing was also discussed at the same meeting of the committee—that is the determination of a practical standard of light. The archaic device upon which the Government still insists is about as definite a standard as the dimensions of the proverbial lump of chalk, and would, doubtless, have been discarded long ago had any really satisfactory substitute at that time offered itself. That a satisfactory standard is now obtainable can scarcely be doubted after the unanimously favourable reports which have been rendered by the most competent and independent judges upon the pentane lamp of Mr. Vernon Harcourt. It is a little amusing to note, however, that the venerable wax candle "consuming 120 grains of spermaceti per hour" has still some firm adherents. At the Society of Arts last week Mr. Williams stoutly maintained that the wax candle was all that the most enlightened could desire, provided only that you took care that the top of the wick was bent in a graceful parobolic curve.

This is a subject which has long engaged attention both on scientific and on industrial grounds, and in any action that is taken by the electrical engineers it will be necessary to bear in mind that the gas interest is at least equally concerned. Mr. Preece, who was Chairman of one of the British Association committees appointed to consider the question, is of opinion that the candle should still be retained as the nominal unit, but that in practical photometry some more definite standard should be employed whose value should be interpreted in terms of the stardard candle. If we rightly understand Mr. Preece, this merely implies that the new standard should be adjusted as nearly as possible to the most probable true value of the old one, and that the term "candle" should be retained. With this we quite agree; but, on the other hand, we do not think that any attempt to compromise the question by introducing a secondary standard, to be compared from time to time with the old candle, would be at all satisfactory.

In connection with the interesting communications from Dr. Oliver Lodge on the electric dissipation of fog (in the correspondence columns of this and the previous issue) we may mention also some recent experiments of MM. Damon and Miquel

Digitized by Google

DE RUI (*Revue Scientifique*). After repeating the original experiments of Dr. LODGE on the precipitation of tobacco smoke and of other fumes, they determined to see whether the same process would prove efficacious for the removal of bacteria from the atmosphere. The experiment met with a considerable degree of success. A measured quantity of air was first passed through a tube one metre long, open at both ends, and having a bulb of 5 centimetres diameter in the centre of its length; the number of bacteria contained in the bulb at the end of a certain interval was ascertained by well-known methods. A static discharge was now caused to take place within the bulb, whilst the experiment was repeated. The number of bacteria which had been retained was then found to have increased in the proportion of about 15 to 4. Other experiments followed, and in the end the authors sum up with due scientific caution as follows:—The only precise conclusion which can be drawn from these experiments is that within a certain space surrounding the poles the electric discharge produces an augmentation in the proportion of bacteria contained in the surrounding air. Without doubt also a certain number of them adhere to the poles themselves, as is the case when any kind of powder is so treated, and, as a consequence, the air is, to a certain extent, deprived of the bacteria which it first contained.

AMONGST other places where the local authorities are stirring in the matter of electric lighting is the town of Derby. Now, at Derby there is already in use a "refuse destructor," in which about 150 tons of *combustible* material (after excluding dust, &c.) are consumed weekly. Assuming that the heating power of this material is only one-third of what would be given by an equal quantity of steam-coal, we shall have a supply of fuel equivalent to 50 tons, or 112,000lb. of coal per week. At the rate of 3lb. of coal per horse-power per hour there is, therefore, an available fuel supply at Derby of 37,000 horse-power-hours, or, say, 220 horse-power continuously at work. It therefore seems highly probable that the Corporation of Derby could light by electricity at least the whole of the municipal buildings at a comparatively moderate cost. Doubtless there are many other places where the same considerations may be applied.

OWING to the American custom of quoting the price of arc lighting at so many cents per lamp per night, the cost is not readily compared with English practice, in which it is customary to quote per lamp per annum. It will therefore be interesting to give the figures for some of the chief cities of the States in the English form, and it will be seen that prices rule decidedly higher than with us. For instance, for a 10-ampere current, Boston pays no less than £47. 9s. per lamp per annum; Brooklyn, £40. 3s.; Philadelphia and Baltimore each pay £36. 10s.; and Buffalo, £32. 17s. In New York, where the competition was very severe last year, the price is at present only £25. 9s., but it is understood that the contract will not be renewed on these terms. The lowest charge on the list before us is at New Orleans, and amounts to £24. 16s., but this is probably for a 6-ampere current.

THE interesting letter of Prof. SILVANUS THOMPSON on the question of flashed filaments (in last week's *Electrician*) suggests one consideration which may tend to some extent to modify the conclusion arrived at. Prof. THOMPSON points out that the effect of flashing is to produce a filament, not of uniform resistance, but of uniform luminosity, and that this involves a greater deposition of carbon at the loop where the filament is subject to radiation from adjacent parts, and a lesser deposition near the clamps, where it is cooled by conduction. This is indisputably true, and it obviously tends to weaken the conductor where it should be mechanically strongest. But, on the other hand, does it not also follow that it is advantageous to the life of the lamp that the filament should be thickest where its temperature is liable to be highest, namely, at the bend? This consideration evidently applies chiefly to lamps with more than one turn in the loop, and it would, therefore, seem probable that for these lamps the advantage—other things being equal—lies on the side of flashed filaments.

FOR a rough approximation the candle-power of an incandescent lamp is often taken as varying as the fifth power of the E.M.F. at its terminals. In another column will be found a Paper showing that the candle-power can be very accurately determined from the current. The table we reprint shows an extremely close agreement between the "calculated" and "observed" columns; so close, indeed, that some captious critics might be disposed to inquire whether the photometrical observations were made before or after the calculation. Figures are very much like oysters, so much easier to swallow when raw than when otherwise. We should also like to know how the author determines "c_0." In the table we reprint, as in the others we do not, "c_0" is about one-third the current at normal candle-power. Now Weber has shown (*The Electrician*, Jan. 27th, 1888, p. 281) that a Siemens lamp taking ·5 A at normal candle-power begins to be visible at ·051 A. In fact, to obtain anything like such accurate results as those given, "c_0" as well as "a," must, we fancy, have been determined from observations with measurable candle-powers. Be this as it may, the law, if it is one, is both interesting and valuable, and we should be glad to hear what our lamp manufacturing experts have to say on the subject.

EVER since last July we have been saying what we could to dissuade investors from putting their money into Mrs. FRIEND'S sugar "shoot;" and in the month of September we did our best to cover the whole business with ridicule. The shares of the company went on rising nevertheless, until only a few days ago they reached six times their nominal value. Probably at this stage the gullibility of the public was exhausted, and then the astute widow, with her accomplices, calmly retired from business into the seclusion of the "Far West." The original capital was $1,000,000, in $100 shares, issued, however, at a very high premium; and taking subsequent transactions into account the total losses must amount to a very large figure. Who the real sufferers may be we have yet to learn; but we confess to feeling somewhat callous as to them in view of the fact that their folly has added one more disreputable scandal to the many burdens with which electrical industry has been saddled.

Digitized by Google

NEEDLESS to say we should have much preferred to see our predictions and warnings falsified. They were based not on any knowledge of the alleged process—for that was kept dark from everybody—but on considerations which ought to have weighed with the simplest of grown-up children. Not to have patented a secret process was suspicious to begin with; to keep back all evidence of electricity taking any part in the process was still more so; and to put it on the English market instead of keeping it in America was a strong indication of bad faith from the very beginning. Other circumstances of a still more shady character connected with the antecedents of the inventor and the invention have since come to light, making it very hard for us to believe that the agents employed by Mrs. FRIEND were as innocent as they would have us believe them to be. The Americans have no high opinion of our business sagacity; but even Americans will prefer to think us knaves rather than credit us with such incredible stupidity as to have been really deceived by the unprofessional relict of the late "Professor" FRIEND. Query: *Is* he dead?

AN English financial journal largely responsible for the booming of this gigantic fraud now asserts that the "*bona fides* of the process remained unquestioned until last week." We suppose that is what the English promoters generally will say. But if this is their belief, it only makes their conduct the more reprehensible, for it amounts to a confession that they neither consulted electrical experts on the subject nor even took the trouble to see what the electrical journals were saying about it.

THERE was once a sensible newspaper man who put a dynamo into his cellar with a gas engine to drive it, and so lit up his office with the beautiful electric light. But twelve months later there came by that way a cunning central station man, and he said: "See, here is a transformer which I have made especially for you; put this in your cellar and you will have a better and a whiter light." So the newspaper man put away his dynamo and his gas engine, and now he says to his friends: "You should use the alternating current, because it gives a whiter light." But he is very angry with the lamp makers, who, it seems, have of late supplied him with a shockingly bad lot of lamps. Moral: Look after the volts, and the lamps will look after themselves.

Amsterdam.—The telephone between Amsterdam and Rotterdam will be opened shortly.

Edinburgh.—Mr. Richard Millar, of St. Enoch's-square, Glasgow, has been awarded the contract for the electric lighting of the Edinburgh Public Library.

Madras.—Extensive tramway schemes are contemplated in Madras, and it is possible that electrical power may be used. Nothing definite is, however, at present settled.

Military Telegraphs.—The *Wiener Tagblatt* states that the Russian fortresses in Poland are all about to be connected with one another by subterranean telegraph wires.

Malvern Link.—The Lighting Committee of the Local Board of Malvern Link have been instructed to ascertain and report upon the probable cost of electric lighting.

The Director General of Indian Telegraphs.—Sir Albert Leppoc Cappel, Director-General of Telegraphs, has been granted 15 months' extension of furlough, at the end of which he will retire.

Military Telephony.—It is reported that the experiments with portable telephones in outpost service during the last manœuvres were so successful that the War Office has ordered a considerable number.

Chiswick.—At the last meeting of the Chiswick Local Board the Clerk reported that the West Middlesex Electric Lighting Company had abandoned their intention to seek a provisional order, authorising them to supply electricity for the lighting of Chiswick.

Holborn Board of Works.—At a meeting of this Board on Monday last a letter was received from the London Electric Supply Corporation asking the Board's assent to the granting of a Provisional Order. The communication was referred to the Committee of Works for consideration and report.

The Govan Election.—Sir William Thomson spoke in support of Sir John Pender's candidature for the Govan division of Lanarkshire at a meeting held in Govan on Monday night. We notice, also, that one of the local journals reprints the biography of Sir John Pender from "The Electrician's Directory."

The Baudot Telegraph.—The Baudot duplex apparatus has now been working between Rome and Turin for some three months, this line being previously served by the Wheatstone. The Baudot quadruplex apparatus will start working on the Rome-Milan line, and perhaps also on the Rome-Naples line, in the course of the present month.

The "Manufacturer."—Judging by the special Christmas number of *The Manufacturer*, which lies before us, this paper certainly makes good its claim to be a representative newspaper of industries, trades, arts, manufactures, and inventions. *The Manufacturer* seems to us a most useful publication, both from the reader's and from the advertiser's point of view.

Pocket Telephone Directory.—The Northern District Telephone Company have just brought out a neat pocket directory, containing the names of the subscribers in the score of towns now served by their system. This little publication also contains details as to the charges for local and inter-urban messages, and a list of call offices open to the general public.

Transformers at the Brighton Central Station.—Mr. Arthur Wright, Managing Director and Electrician of the Brighton Electric Lighting Company, writes as follows:—"Will you kindly correct an item in the last issue, in which it is implied that we use exclusively Mordey alternating apparatus, whereas we have tried all forms viz., Kapp, Mordey, Lowrie-Hall, and lastly our own."

Election of County Councillors.—The Council of the London Chamber of Commerce at its last meeting decided to recommend to members the desirability of only supporting candidates for the London County Council on non-political grounds, and to urge them to give their votes to those possessing commercial experience, or known to be intimately acquainted with the interests and requirements of the business community of the City.

Armstrong's Improved Fastenings for Bolts and Nuts.—The Walsall Electrical Company have recently brought out an improved fastening for bolts and nuts, the special feature of which is a cap which falls over the nut, rendering rotation impossible. The arrangement is very simple and the additional cost is compensated for by the fact that frequent inspection and screwing up is avoided. The cap is also useful in protecting both the bolt and nut against corrosion.

St. Luke's Vestry.—At the last meeting of this Vestry a letter was read from Messrs. Deacon, Gibson and Medcalf, on behalf of the London Electric Supply Corporation and Electric Lighting Company, notifying their application to the Board of Trade for a provisional order to supply electric light in the parish of St. Luke's, and the asking the Vestry's consent to the proposal. The letter was referred to the Parliamentary Com-

Digitized by Google

mittee. The Vestry at their former meeting were not opposed to the introduction of the electric light in the parish.

"Anti-Friction" Steam Packing.—We have received from Messrs. D. G. Cresswell and Son, of Bradford, a copy of their latest catalogue and price list. From the preface we gather that Messrs. Cresswell and Son have paid great attention to the manufacture of steam-packing, and now produce a packing which they claim will stand any pressure or degree of heat without altering its lubricity and elasticity. The catalogue also contains a long list of asbestos articles supplied by this firm, such as "asbestchouc" sheeting, asbestos cement, asbestos carbon for filters, &c.

An Electricity Counter.—We have recently had an electric counter, manufactured by A. Hubert, of Lausanne, brought under our notice. The apparatus is very simple and compact, consisting merely of a train of clockwork enclosed in a circular brass box. The clockwork is set in motion by the action of an electro-magnet, and the number of minutes, hours, tens of hours, and hundreds of hours the current is on is recorded on four small dials. The counter is one which would sometimes be of use on arc-lighting circuits, or in other cases where the energy supplied is constant in quantity.

Proposed Electric Lighting of Derby.—At the meeting of the Derby Town Council on Wednesday, the Mayor (Mr. Woodiwiss) mentioned that he had recently received communications from electricians submitting proposals for lighting the streets. He thought it would be best to refer the matter to the Parliamentary Committee for consideration, and moved accordingly. A brief discussion ensued, in which some members expressed the hope that the question would be fully looked into, and others were altogether hostile to the proposal, and objected to expenses being incurred. In the end the motion was approved.

Exports of Telegraphic Wires, &c.—The Board of Trade returns issued this week give the results for the last month of the year and for the twelve months. The following is a comparative statement of the exports of telegraphic wire and of apparatus connected therewith. The monthly details of former returns have been given in previous issues:—

	1886.	1887.	1888.
December	£42,349	£36,535	£33,707
Twelve months...	992,667	817,385	521,174

It will be observed that the unsatisfactory nature of last year's returns has been maintained up to the close.

The Commercial Cable Company.—The officers and staff of the Commercial Cable Company presented their president, Mr. J. W. Mackay, at Christmas time, with a handsome testimonial, which took the form of a silver centre-piece emblematical of cable enterprise. This presentation was especially made to commemorate the fourth anniversary of the opening of the cables, and was accompanied by an illuminated address. A few days previously, Mr. Mackay, who was staying at San Francisco, telegraphed to the General Manager at New York to the effect that he was not to forget the usual annual Christmas present to the cable staff of half a month's salary.

Messrs. Laing, Wharton and Down's Annual Supper of Employes.—The annual supper of Messrs. Laing, Wharton and Down's staff took place on Saturday, the 29th ultimo, at the Queen's Arms Hotel, Queen-street, E.C. An excellent repast was served up, after which the toast of "The Queen" was duly honoured. The continued prosperity of the firm was proposed by Mr. W. J. L. Sandy, and drunk with cheers. Mr. D. C. Bate, who presided, in conveying the thanks of Messrs. Laing, Wharton and Down to the whole staff for the way in which they had worked throughout the past year, took occasion to remark that contracts were on hand which would give full employment for several months, and that the prospects of electric lighting generally appeared more hopeful than had ever been. Other toasts, interspersed with songs, followed, and a most enjoyable evening was spent.

The Electric Light and Vision.—Dr. G. M. Gould, of Philadelphia, has written an interesting Paper, entitled "Is the Electric Light Injurious to the Eyes? (*Medical News*, December 8th) in which he sums up to the effect that this "light of the future" has not been proved to be injurious, except in the case of those "who approached it very closely, gazed at it protractedly, and without protecting coloured spectacles." There is no justification for the popular prejudice against the use of the diffused light as an illuminant. If, however, people will persist in examining the naked arc with the naked eye, it appears that the result "is characterised by temporary retinal paralysis, by blepharospasm, central scotomata, chromatopsia, &c., and is marked by intense photophobia, lacrymation, conjunctival congestion, &c. The attack usually lasts two or three days, the treatment being cocaine and atropine, and cold or hot compresses."

Electric Light Failures in Spanish Theatres.—Spanish advices state that on December 28 a special performance was to have been given in the Apollo Theatre, Madrid, but that it had to be abandoned owing to the failure of the electric light. Later advices state that the defects having been remedied, the Zarzuela Theatre was reopened, but that both it and the Apollo Theatre had to be closed again on the 2nd inst. The *Dia* says that the matter has been referred by the civil authorities to the consideration of the Theatrical Board, with a view to the presentation of a report upon the failure of the light, which is described as having not only prejudiced the companies, but, it is feared, has also been dangerous to the public. Nothing is said of the prejudicial effect of these avoidable difficulties upon the advancement of the electric lighting industry. It may be truly said of the electric light, both here and abroad, "Save me from my friends."

The Lighting of the City.—At the meeting of the City Sewers Commission held at the Guildhall on the 8th inst. the Chairman of the Streets Committee stated, in answer to a question, that the subject of electric lighting for the City had been under consideration for some time by the persons to whom it had been referred—namely, the engineer, the solicitor, and Mr. W. H. Preece. The engineer had done his part of the work, but some details remained to be settled between Mr. Preece and the solicitor. This settlement was, however, very near, and the Commission might expect a report at an early date.—Mr. Morton complained very strongly of this matter having, as he said, been played with far too long. There would be a new commission directly, and a fresh committee, who would, doubtless, feel it their duty to go into the matter from the beginning, at an enormous expense and a great loss of time. —We may add that the report furnished by Mr. Preece to Lieut.-Col. W. Haywood is of a confidential character.

Bath.—At a meeting of the surveying committee of the Town Council, held on Monday, 31st December, the following letter was read from Mr. H. St. John Winkworth, secretary of the House-to-House Electric Light Company (Limited):—"17, Bishopsgate-street Within, London. We beg to apply to your Corporation for their sanction to an application by this company to the Board of Trade for a license for seven years to supply electricity for lighting purposes, to be distributed by means of underground mains within your city. In making this application we beg to state that our company has just constructed the first central station in the metropolis for the accomplishment of distinct lighting throughout an extended area by means of underground mains under the superintendence of its founders, who in their Eastbourne institution enjoy the unique distinction of being the only engineers in the world who have so far accomplished this, and worked it uninterruptedly for the past six years." The matter was referred to the Electric Light Committee.

Caustic Potash and Bromine Elements.—According to Herr Koosen (Wiedemann's *Annalen*, Vol. XXXII., pp. 508-515), when caustic potash is employed in a Daniell cell instead of acid, its action is as follows:—1. KHO is decomposed, giving K, O and water. 2. K replaces zinc, forming sulphate of potash instead of sulphate of zinc. 3. Zn is oxidised by the liberated oxygen. 4. The zinc oxide thus formed is dissolved into the undecomposed KHO solution. Of these four reactions 1 diminishes the E.M.F., 2 and 3 strengthen it, as possibly does 4. The E.M.F. obtained in practice agrees well with theory. A Daniell cell made up with tolerably strong caustic potash remains very constant on a high external resistance. Caustic

Digitized by Google

soda answers still better, as it dissolves the zinc oxide more freely. It is important to avoid diffusion as much as possible, and for this purpose Herr Koosen prefers to employ two porous pots, one inside the other, with the space between filled with a solution of sulphate of soda or potash respectively. He also mentions a zinco-bromide-platinum cell without porous pot which he has found to remain constant on closed circuit for months together; the bromine is covered with a layer of paraffin oil.

Christmas Festivities and the Electric Light.—At this season of the year the hospitals in the Metropolis are in the habit of giving entertainments to those who, perhaps unfortunately for the time being, are inmates thereof. To good work of this description the medical staff, nurses, students, and many of the outside public always lend a willing hand, and everything that adds to the attractiveness of the scene naturally helps to ensure the success of the undertaking. In this connection a novel feature was introduced into the entertainment given by the West London Hospital on the 2nd instant, when a large Christmas Tree was lighted by electricity, the form of lighting taking the shape of incandescent lamps interspersed amongst the foliage in a very effective manner. This work was carried out by the Woodhouse and Rawson Electric Manufacturing Company, whose premises are close by the hospital, at, it is needless to say, their own cost, and the whole work was completed in a remarkably short time. The artistic result was highly appreciated by the large company who had met to assist the secretary and staff in their pleasant task of endeavouring to alleviate in some degree the sufferings of their less fortunate fellow creatures, and in this they were evidently successful, as the patients appeared extremely gratified at the well-arranged programme provided for them, intermixed, as it was, with some excellent music.

Globular Lightning.—At the present time, when all questions connected with lightning are so much discussed, the following instances of globular discharges, which are said to have been observed at Hirschberg, in Silesia, during the storms of April 19th and 29th of last year, will prove of interest. During the first storm a woman and her son were looking out of two different windows of their house, when they noticed a yellowish ball of fire, about the size of a skittle-ball, moving slowly along the telegraph wires with a noise something like that of a flag rustling in the wind. After falling on to the grass-covered square the fire-ball again rose and disappeared rapidly over the roofs of the opposite houses in a S.S.W. direction. A similar phenomenon was observed by a woman who was looking out of a window facing the east. A fire-ball passed in front of the window from south to north, at a distance of some 20 metres; it then rose towards the roof of a house provided with a lightning conductor and disappeared, leaving no trace of its track. The ball was about the size of a child's head, of a yellowish colour, and no noise was heard. This ball is said to have been followed by a row of fire-balls about the size of billiard balls. The storm of the 29th April was extremely violent, and the lightning was of an extraordinary character. During the progress of the storm a brilliant globe of fire was seen to fall from a cloud upon Hirschberg, and to burst in mid-air. During the same storm a fire-ball was seen by a gardener at work in the garden of the Lycée, and by a young girl some 50 metres distant. According to the former, a reddish ball of fire came suddenly over the roof of the Lycée with a whistling noise, and exploded noiselessly over the trees in the garden, the fragments falling towards the earth in all directions without leaving any traces.

Electric Lighting in Kimberley.—The *Eastern Province Herald* of December 5th contains an interesting account of the flourishing condition of electric lighting in Kimberley. Some plant which had been unsatisfactorily tested in Port Elizabeth was purchased in 1884 by the municipality and removed to the Diamond Fields, Mr. Cousins being appointed as borough electrician. There are upwards of forty arc lights distributed through the main thoroughfares, which are connected with two dynamos. Mr. Cousins has since erected separate installations for the Queen's Theatre and Hershfield's bar, and for the shops of Messrs. Store Brothers. These are lighted by incandescent lamps only, except a solitary arc light in the front of the theatre. In 1866 the directors of the De Beers Mining Company determined to introduce the electric light, and two circuits were erected under the guidance of Mr. R. O. G. Drummond. Subsequently three other circuits were erected, and another is shortly to be commenced to light the underground workings. The engine, boiler, dynamo, and other accessories for this extension have been ordered from England. Up to the present date the wires from the dynamos to the extreme limits of the several circuits measure upwards of ten miles, and when everything is running there are 29 arc lamps of 1,000 candle-power each, 59 Bernstein lamps of 16 candle-power, and 24 Edison and Swan lamps of 16 and 8 candle-power. The engine house and dynamo rooms are constructed of galvanised iron. The engine is of 25 horse-power, furnished by Messrs. Marshall and Co., and is provided with Hartnell governors, sight-feed lubricators, and other latest improvements. In the room adjoining there are three Elwell-Parker dynamos, supplying ten arcs each; two Brush dynamos, supplying twenty arcs each; and a small supplementary dynamo, supplying the current to the incandescent lamps in the engine and dynamo rooms in the private dwelling-house of the resident electrician, and to eight accumulators. The circuits are arranged so that they can be run off any one of the machines, and they can also be all connected in series when necessary. Woodhouse and Rawson's magnetic cut-outs are used, and a switch is provided by which the wire circuits can be connected to earth in a moment in the event of a thunderstorm. The station is also well supplied with ammeters (Slatter's) and voltmeters (Cardew's). The Bernstein system appears to give every satisfaction, and is considered a great improvement upon the old system of incandescent lighting.

Electric Lighting in Birmingham.—The sub-committe of the General Purposes Committee of the Corporation which has this matter in hand met on the 3rd inst., and settled the recommendations on which its report to the General Purposes Committee will be founded. We understand, says the *Birmingham Post*, that several important amendments of the draft Provisional Order submitted by Messrs. Chamberlain and Hookham were agreed upon, affecting, amongst other things, the amount of capital required for the undertaking, and the formation of a company. These and other points, it is understood, will be discussed with the promoters before the report is formally prepared, and possibly an agreement may be arrived at. The report will then be discussed by the General Purposes Committee, and will be presented to the Council early in February, as the consent of the Council must be given in that month or the Provisional Order cannot be obtained next session, and the town will then have to wait for at least another year before any serious attempt is made to provide a system of electric lighting. The *Birmingham Gazette*, referring to the same subject, says:—Mr. Henry Lea, of the firm of Messrs. Henry Lea and Thornbury, consulting engineers, in a report to the Electric Lighting Sub-Committee, makes, we believe, the following recommendation:—"Overhead electric lines not to be employed within the borough of Birmingham, excepting with the special consent of the local authority, and then only for a short period, say for two years, in each case in which it may be desired to use them. They are to be employed only as pioneers for ascertaining the extent of the demand in new districts prior to laying down the electric lines permanently underground. The approval of the local authority to be necessary as to the method and details of construction and insulation of all overhead wires before they are proceeded with." After referring at some length to the arguments for and against the employment of overhead wires, the *Gazette* concludes its remarks as follows:—"These arguments, so far as they support the desirability of allowing a temporary use of overhead wires, seem to be well grounded. Of course all that is said about inconvenience to the electric lighting companies would go for nothing if the danger from overhead wire were as grave and pressing as the alarmists make out; but the evidence does not satisfy us that it is. On the contrary, the risk seems to have been exaggerated, and the public may therefore wait with comparative equanimity the probable decision of the committee in favour of the use of overhead wires for purely pioneer and experimental purposes."

NOTES ON ELECTRO-MAGNETIC INDUCTION.

BY DR. J. A. FLEMING, M.A.

(Continued from page 245.)

§ 8. *Magnetic Screening and the Action of Metallic Masses in Induction Coils.*—If a primary and secondary coil are separated by a metallic sheet, Henry found* that a notable decrease took place in the intensity of the *shock* taken with this arrangement. A thick plate was found more effective than a thin one in thus preventing the inductive effect of the primary upon the secondary coil. If a slit was cut in a circular plate the annulling effect was altogether stopped. If the two edges of the gap (*see* Fig. 20) were furnished with wires leading to a magnetising spiral, Henry found he could in this way make evident the existence in the plate of a current induced by the action of the primary. A flat coil of insulated wire was substituted for the metal plate, and it was found that the screening action of this coil was only sensible when the two ends were joined so as to complete the circuit. This action, by which the induction of a primary coil on a secondary is prevented by the interposition of a metallic plate cylinder or closed circuit of insulated wire, is called *magnetic screening*. The elementary explanation of this effect is not difficult to arrive at. Suppose a small conducting circuit of resistance R to be placed in a magnetic field so that it is traversed normally by N lines of magnetic induction. Let the constant coefficient of self-induction be L. If, then, in any small time dt a variation of the lines of induction traversing this circuit takes, place the impressed electromotive force on that circuit will be represented by $-\frac{dN}{dt}$, and if at that instant the current in the circuit is i, by the principles laid down in the last chapter, the current equation will be

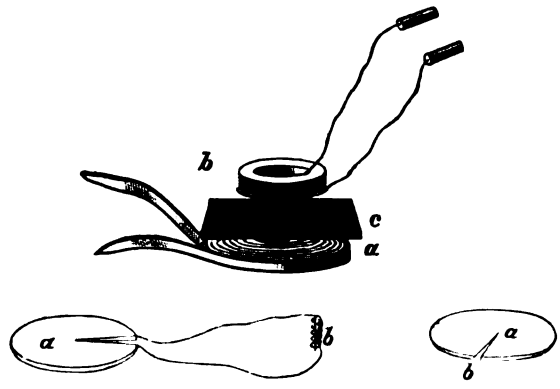

Fig. 20.

$$L\frac{di}{dt}+Ri=-\frac{dN}{dt}$$

or

$$\frac{d}{dt}\left(Li+N\right)+Ri=0.$$

Suppose the conductivity of this circuit to be perfect, and R therefore zero, we have, by integration of the above equation, the result

$$Li+N=\text{const.};$$

in other words, the lines of induction Li, added to the circuit by the induced current generated in it, are *opposite* in direction to those whose variation is producing it, and together with them make up a constant number. Hence, if the variation of N is such as to take lines of induction out of the circuit, the operation of the current thereby induced is to add or increase them in the circuit at an equal rate. If we suppose our circuit to be a perfectly conducting metal plate, and just behind this metal plate there is another small closed circuit, then any variation of lines of induction passing through this plate will not take effect in producing any induction current in the small circuit, because the operation of the current induced in the plate nullifies, as far as the small circuit is concerned, any variation of the external field. It is clear that these conclusions would apply to any surface of finite extent which possessed perfect conductivity; the induced currents which any variation of the external field would produce in this surface would always be such that the induction through each portion would be kept constant—in other words, that the perpendicular component of the magnetic induction at each point on the surface would retain a fixed value. It follows that a closed surface of zero resistance is a complete screen for all points in the interior against the effects of variation of the field on the other side of the surface; these effects reduce to the production of surface currents, which keep the field in the interior constant or at zero.

Faraday describes ("Exp. Researches," Vol. I., § 1720 *et seq.*) an experiment which at first sight seems to disprove the fact of magnetic screening. He placed a flat copper wire spiral, which was in connection with a battery and key, between two other flat spirals which were respectively connected with the two coils of a differential galvanometer. The coils were so joined up that the inductive effect of a break and make of the battery circuit produced no movement of the galvanometer needle because it was subjected to two equal and opposite impulses from the two coils. When an exact balance was obtained a flat plate of copper, nearly three-quarters of an inch thick, was interposed between the primary spiral and one of the secondaries. The galvanometer needle was not, however, any more affected than if the copper was away. To understand this we must bear in mind that the break or make of the primary current produces in the copper a secondary current, but as the effect of the primary coil on the secondary coil on that side is balanced by the other one we may regard the secondary coil next the copper plate as free to receive any inductive effect it can from the eddy current induced in the copper block. This secondary current induced in the copper generates a *tertiary* current in the secondary spiral, and this tertiary current consists, as we have seen, of a double short flux of electricity equal in quantity and opposite in sign. The galvanometer there is traversed by two equal small quantities of electricity in opposite directions, and as this does not sensibly affect a not very sensitive galvanometer no movement of the needle is seen. If, however, instead of the differential galvanometer Faraday had used a differential telephone he would have found distinct evidence of a screening action. Again, suppose that, instead of a simple make or break, Faraday had employed a steadily periodic or alternate current in the primary, this would have set up a steady periodic secondary current of equal frequency in the copper plate, and this again would have set up in the secondary coil on that side a steadily periodic tertiary current of equal period, and this might have been detected by the use of a differential electro-dynamometer or a soft iron needle galvanometer.

Henry found that a sheet of tinfoil afforded a very small amount of screening for shock, but a thick sheet of copper a very considerable one in the case of induction by battery currents, and in the case of induction by Leyden jar discharges the same phenomenon was apparent. In the case of an iron screen there is an additional effect, due to the fact that the iron, by its small magnetic resistance, conducts away the lines of induction somewhat through its mass, and prevents them from extending to the space on the other side. In this case also a considerable thickness of metal is necessary to bring about the effect of annulment. In the case of Sir W. Thomson's ironclad galvanometer a very thick shell of iron is necessary to annul all permanent field in the interior space. When we are limited to the use, as we are in practice, of materials whose conductivity is far from being perfect, it is found that a thin screen of metal hardly affords any sensible protection from inductive effect. In other words, the field on the other side of the screen is very far from constant.

(To be continued.)

ELECTRIC LIGHTING IN THE CITY OF LA PLATA, SOUTH AMERICA.

BY W. R. CASSELS.

The story of the creation of the city of La Plata, the new capital of the province of Buenos Ayres in the Argentine Republic, reads like a chapter of romance. Five years ago the province of Buenos Ayres gave up its old capital to the nation and set out to found and build a new one for itself. All the energies and resources of the Government of this wealthy and prosperous province were brought to bear on the work, and in an incredibly short space of time a city of large area, with noble public buildings, elegant private residences, and spacious boulevards began to rise upon a site that until then had been open ground. Some idea of the babel of confusion that prevailed in the early days of the city may be formed when it is understood that the task was accomplished in the space of four years. Houses were springing up here and there isolatedly, but regular rows took long in forming. Immense piles of bricks and building materials lay scattered everywhere, and the streets were nothing but mud and ruts. At an early stage light was necessary and plenty of it, and the opportunity for introducing the electric light was still more favourable in view of the difficulties that were presented for the employment of the ordinary methods. Four towers, roughly constructed with the trunks of eucalyptus trees, were erected at a distance of several hundred yards apart, and arc lamps of 4,000 candle-power gave ample illumination to the busy scene. As the city progressed, and the buildings assumed proportions, and the streets became defined, the wooden structures were replaced by one central iron tower 150ft. high, and a few isolated lamps on poles.

So successful was this initiatory lighting found, and so well adapted to the peculiar conditions of the city, that after a careful study of the best form for its application, and of its cost as compared to that at which gas was offered, the authorities unhesitatingly decided that the electric light should be definitely adopted for the entire public illumination of the city. A contract was therefore entered into with Mr. W. R. Cassels for the establishment of 200 arc lamps of 2,000 candle-power each. The installation of these was completed in July, 1886; but so rapid had been the growth of the city that the number was now found insufficient. Meanwhile, however, a gas company had been organised, and a large gasometer erected by a syndicate of capitalists, who took the cities of London and Paris for their model, and hence were sceptical regarding the eventual progress of electricity. Strenuous efforts were made by them to obtain at least a part of the public lighting contract, and gas was offered of a better quality and at a lower price than it was supplied anywhere else in the country. Twelve months were allowed to pass by before a decision was taken. Political influences and personal interests were brought to bear on behalf of the gas, which had already been favoured by the previous Government with a grant of several acres of valuable land. The fight ran high and warm, but the true interests of the city prevailed, and the contract for electric lighting was finally doubled, and gas entirely excluded.

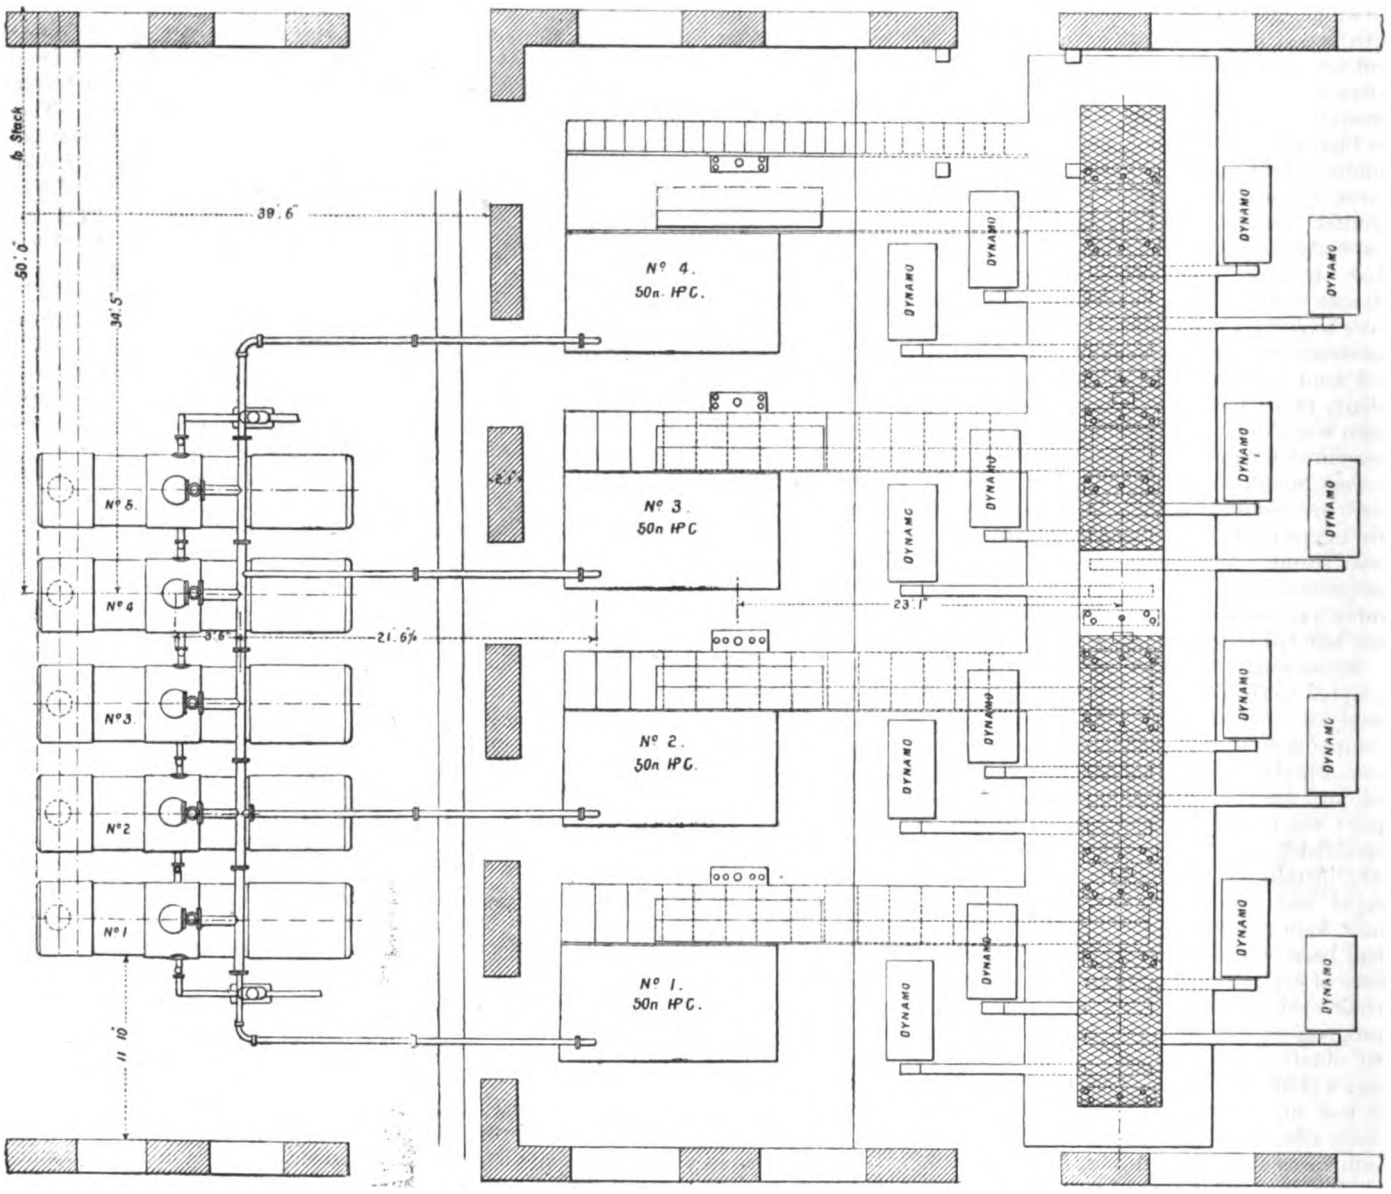
A short description of the present electric light installations at La Plata cannot fail to be of interest. La Plata is one of the few cities, perhaps the only one, the United States not excepted, that relies entirely upon electricity for the supply of public lighting on a large scale, and was not only the first city in South America to adopt the electric light, but even at the present day is, perhaps, the only example in the world where gas, although at hand, with an abundant and excellent supply, is not employed at all for street lighting. This result is in a great measure due to the fact that ever since its definite installation the electric light has given the most complete satisfaction, and with one solitary exception has never suffered an interruption. The exception was during a severe thunderstorm, before a system of lightning arresters had been applied, when several of the dynamos were injured by atmospheric discharges, and the light was extinguished for several hours. The plan upon which the city is built and laid out contributes also, no doubt, to the advantage of employing arc lamps and to the economy of the lighting. As is usual in all modern American cities and towns, the streets are all laid out in regular blocks with a frontage ranging from 85 to 130 yards, and one arc lamp placed upon a pole located at each intersection of the streets will illuminate equally down four different streets. If the city had been laid out especially with a view to its illumination by means of arc lamps it could scarcely have been improved upon. Each post is about 25ft. high, and the width of the streets admits of their being placed in the middle without interfering with the traffic; indeed in many cases the centre of the boulevards is occupied with a garden. Ordinary pine posts were used at first as a support for the lamps, but these are being replaced in the principal streets by iron structures. The cables are all overhead, and for the most part are carried on posts placed at the edges of the sidewalks. This method ensures safety, and greatly facilitates the maintenance of the circuits in good order. When the light was first laid down each lamp was enclosed in a lantern fitted with Trotter's dioptric glass, with the idea of softening the rays and counteracting the deep shadows; but since the public have become used to the light it is found that clear glass, or nearly clear glass, is preferred. La Plata suffers greatly from dust, which at certain seasons becomes most trying, and penetrates into every crevice even of the houses, and sweeps down in storms over the city in suffocating clouds. The arc lamps thus exposed must necessarily be of the simplest and least intricate construction, and the improved Brush type is found to answer very well—at all events, for the street lighting. The total number of arc lamps employed for the public service is at the present moment 258, and over one hundred additional lamps are furnished to private consumers, without speaking of the large number of incandescents. With the additions now contracted for and in process of being laid down the total number of arcs will be considerably over 500.

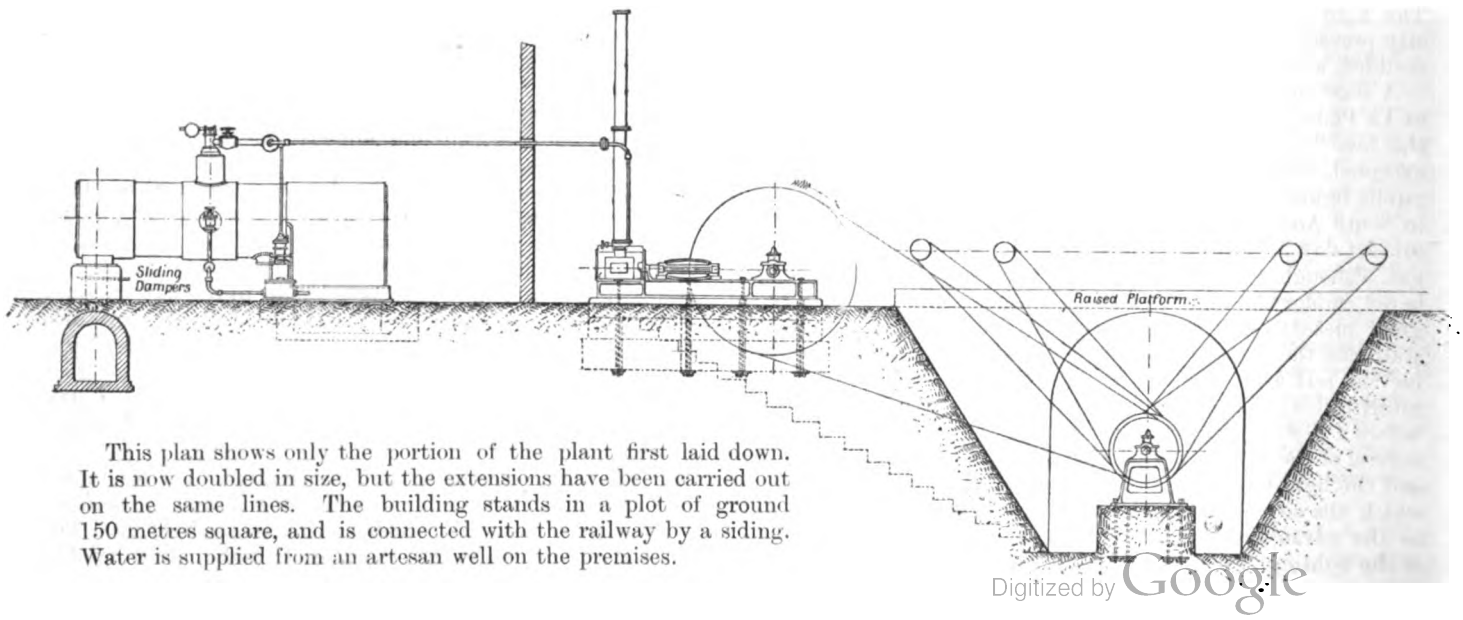
All the principal buildings use the electric light, among them the following, all supplied from the central station:—The two theatres, one bank, police building, the Legislative building, the Tribunals, the railway stations, all the principal shops and restaurants, the residence of the governor and other officials, and several private houses. Previous to the introduction of the more modern and perfect method of distribution, incandescent lamps were supplied in series and multiple-series from the arc circuits; but arc lamps were always supplied in preference when possible, several reception rooms in private residences, not to speak of billiard rooms and saloons, being thus illuminated. It has been noticed that familiarity with the electric light, and especially the arc light, created a demand on behalf of the public for more abundant artificial light than is usual, so that when gas is employed larger burners and more numerous are asked for. The inhabitants of La Plata when visiting other cities complain of the want of light. A fine is imposed by the municipal authorities for each lamp that becomes extinguished or operates in an unsatisfactory manner. It is interesting to know the number of fines thus imposed. In the year 1887 the average number of public arc lamps employed was 210, representing 75,600 distinct lightings of lamps during the year. Fines were imposed on only 156 of these, or less than ·02 per cent. The service in La Plata has been, in fact, more satisfactory and less subject to fine than any gas service in the other cities of the country. This regularity of service is greatly due to the method of running the circuits already described, but a complete system of watching and registering the behaviour of each lamp is kept up, and no sooner is a lamp reported as faulty than it is at once attended to. A complete record is thus maintained by the contractor of the nightly working of each lamp. Two watchmen on horseback parade the streets during the night, and their report serves as a guide to the day linesmen and trimmers for any work that may be needed. The unskilled labour employed consists of native and Italian "peones," who are found steady and faithful. One man can clean the glass and trim the carbons of forty to forty-five lamps in a day, which seems good work, as poles have to be climbed to get access to the lamp.

The adjoining plan shows the arrangement of the machinery in the station, of that part at least which has been in operation for some time past, and which relates to arc-lighting. The four engines are compound horizontal, each indicating 150

Digitized by Google

horse-power, supplied by Messrs. Davey, Paxman and Co., of Colchester. A main countershafting extends down the whole length of this part of the station, under the floor, and each engine is connected thereto with driving belts. On the fly-wheels of the engines is a loose pulley, or ring, and striking-out forks, worked by screw gear, are arranged to take off or put on any engine. All four engines are generally used to drive the countershafting up to midnight, when one is taken off. At





This plan shows only the portion of the plant first laid down. It is now doubled in size, but the extensions have been carried out on the same lines. The building stands in a plot of ground 150 metres square, and is connected with the railway by a siding. Water is supplied from an artesan well on the premises.

Digitized by Google

any moment, as will be seen, however, any one of the engines can be stopped if required. By this method the work continues uninterrupted under all likely contingencies that may arise. Sixteen dynamos, some of 28-arc capacity, and some of 40, are placed in four rows down the room, and are driven from pulleys on the countershaft below. Two of these are in reserve, and can be switched into any circuit at a moment's notice. As a matter of fact it has been found that trouble or difficulty is more likely to arise from the engine side than from the dynamos, although either is a very rare occurrence.

Brush dynamos were originally laid down, and, generally speaking, this type has been adhered to. The original machines used in La Plata immediately after its founding some five years ago are still running in perfect condition, and have worked almost without any intermission every night since.

Coal, of course, is a very heavy item in that country, costing about 44s. per ton, and the water supply is not sufficient to admit of condensers. The average hours of running during the year 1887 for the street service was 11·54 per day, and according to the log kept the average consumption of coal in the same year was 3·05lb. per actual horse-power.

The success of this installation, from both a commercial and technical point of view, has been quite satisfactory. The contractors have been fully alive to the importance of avoiding anything approaching a failure, when this excellent opportunity of proving the value and efficiency of the electric light for street purposes was put into their hands, and they have now in consequence had other valuable contracts entrusted to them in South America. A great deal is due also to the enterprise and liberal spirit of the authorities in La Plata, who were bold enough to depart from the ordinary routine in contracting for the lighting of their city, and allowed electricity a fair opportunity of proving its worth.

REVIEWS.

Dynamo-Electric Machinery: A Manual for Students of Electro Technics. By Silvanus P. Thompson, D.Sc., B.A. Third Edition, Revised and Enlarged. (London: E. and F. Spon, 1888.)

There is no more distinctive note of the difference betwixt the technical journalism of Europe and of America than that of the relative standard of criticism which prevails on either side of the Atlantic. In America it is scarcely too much to say that technical criticism does not exist. A wide course of reading in Transatlantic periodical literature does not bring to our recollection a single instance of any other than indiscriminate eulogy of the products of native talent, whatever their intrinsic merit—a remark which applies both to the literary and the practical fields of labour. On this side of the ocean, and especially in our own country, it is the rule to attempt at least a more discriminative criticism. If a technical work be altogether worthless it seldom escapes a pronouncement of condemnation. The mediocre or merely respectable treatise may be passed over with a brief commendation, but a work of distinguished merit dealing with a subject of importance may confidently expect to receive an examination which, even if thoroughly appreciative—and *because* it is appreciative—yet seeks to discover in what particular room is still left for improvement.

So much by way of preface to a brief notice of the third edition of a work which beyond all dispute remains the only adequate and generally trustworthy manual on the subject of which it treats. The name of the author would alone be a sufficient guarantee that the volume is throughout informed with the scientific spirit, though, perhaps, the most noteworthy feature of this book (considering that it comes from the laboratory and not from the workshop) is the remarkable acquaintance with the minutiæ of practical detail which is so conspicuously exhibited. The book is one which no student of electrical engineering can at all afford to neglect, and it is also one which can scarcely be read without admiration for the extent and intimacy of the author's acquaintance, alike with the history, the practice, and the theory of his subject.

The important advance which the last two years has witnessed in our customary mode of regarding the phenomena of electro-magnetism had rendered it inevitable that the third edition of Dr. Thompson's work should differ very materially from that of 1886. It has become difficult to realise the fact that little more than two years ago the fundamental conception of the magnetic circuit, if not entirely unknown, certainly did not enter into the calculation of practical men; even transformers were then only beginning to be built with closed iron cores. The extensive change which has taken place in this direction has rendered necessary the addition of several chapters and the re-writing of others, and we now find a complete and lucid exposition of the magnetic circuit. The author, with characteristic industry, has also explored the history of the idea, and we learn, though without much surprise, that more or less explicit references to the general notion of the magnetic circuit are to be found in the writings of at least half a dozen of the early experimenters on magnetism.

Cumming, in 1821, talked of magnetic conductivity, but De la Rive seems to have been the first to employ the phrase "a closed magnetic circuit." The credit of having first perceived the importance of the conception in reference to the design of dynamos seems, however, properly to belong to Lord Elphinstone and Mr. Vincent (see *Proc.* Roy. Soc., XXIX., p. 292, 1879, and XXX., p. 287, 1880), whilst it is well known that the Brothers Hopkinson and Mr. Kapp were the first to formulate a quantitative treatment of the idea.

Speaking of the author's historical researches, we may add that a most valuable and comprehensive account of the early history of the dynamo has been appended to the introductory chapter. In this, as in other parts of the work, Dr. Thompson sets an example which is far too much neglected in the scientific literature of this country — that of quoting chapter and verse for his authorities. The introductory chapters have been re-written, the somewhat abrupt display of diagrams of typical machines which characterised the early pages of the former editions having now been avoided.

The description of dynamos of every imaginable design extends over seven chapters (five in the second edition), and contains more or less detailed reference to no less than 150 machines. It has evidently been the author's desire to confer immortality upon every individual who has been clever enough —or weak enough—to secure a patent for a dynamo of his own invention (?) This is very good-natured of Dr. Thompson, though we do not quite see what useful purpose it serves. A new and more extensive classification of machines has been adopted, as follows:—Closed coil type (*a*), ring armature dynamos (*b*), drum armature dynamos (*c*), disc armature dynamos, open-coil type, unipolar type, alternate current machines. In subsequent editions the last-named category will no doubt be sub-divided into machines (*a*) with and (*b*) without iron in the armature.

This section of the work contains a fund of detailed information of the greatest value. The only slip of any importance that we have noticed is in connection with the distribution of potential around the commutator: on page 68 the author says that in a well-arranged machine of the Gramme type the rise of potential from the negative to the positive brush should give when plotted a curve of sines. But on page 104, when speaking of the methods of obviating sparking, he dwells upon the importance of so shaping the pole-pieces as to obtain a uniform field immediately under either brush—which is of course the proper thing to do, although it is fatal to the preservation of the sinusoid.

There is, however, a graver question which we feel bound to raise at this point. In spite of all the information *about* the behaviour and construction of machines, we are disappointed to find that the author does not attempt to treat systematically of their design. It is true that some account is given of the methods of calculation introduced by Hopkinson and Kapp, but the author has not thought it necessary to shape them into a form which might have served for the direct guidance of the student in the design of dynamos and motors. We believe it to be true that this is a branch of the subject of which nothing approaching a competent knowledge can be gained without a good deal of practical experience. Still, we venture to think that the

Digitized by Google

author might well have formulated the subject in such a way as to distinguish between what is known and can be imparted upon paper, and what must be sought for in experience. The method of procedure, in which is combined the outcome of the soundest scientific knowledge with the necessary degree of reliance upon the results of previous practice, might, at least, have been pointed out to the student with considerable advantage.

Turning to the chapter on the "Elementary Theory of the Dynamo," we find that Dr. Thompson has abandoned his $4\,n\,A\,H$ expression (where A was the equivalent effective area of the armature coil) for a fundamental equation of a somewhat more general character. We may mention in passing that an interesting application of the former expression is to be found in the Paper by Mr. Caldwell on the "Regulation of Dynamos by means of a Third Brush" (*Electrician*, December 28, 1888, p. 217). Dr. Thompson, however, now prefers to write

$$\text{(average)}\ E = n\,C\,N,$$

which is a modification of the form first introduced by Mr. Kapp, and in which n is the number of revolutions per second, C the number of conductors on the armature counted all round the periphery, and N the whole number of lines of magnetic force that traverse the armature core. Now, if we could only find out how to obtain the required value of N with the same degree of ease and certainty as the remaining terms in this expression, the practical design of dynamo machinery would be reduced to the utmost degree of simplicity; but unfortunately this is just what we can by no means accomplish, and, in fact, the whole question resolves itself into the attempt to determine beforehand by calculation what the actual value of N will be under the assumed conditions of construction. The problem is, in simple truth, incapable of anything more than a roughly approximate solution, except by reference to curves directly plotted from experiments carried out upon the iron carcase of the machine. Thus we are thrown back upon the method of Hopkinson, whose merit consists in the fact that it is independent of any assumed function of magnetisation, such as the tangent formula of Kapp (which in practice usually gives a characteristic which first rises too fast and then drops too rapidly), or even the "dia-critical" formula, which is favoured by the author. As for the latter formula—which was independently discovered by Drs. Thompson and Frölich—it is undeniably pretty, and has also the merit of simplicity; but since it involves at least two special experimental determinations, it cannot claim to be free from empiricism. We have not yet seen a curve plotted from this formula compared with the results of experiment.

Apart, however, from the question of designing, the treatment of the mathematical section is most instructive, and both the analytical and the graphical solutions are of the highest educational and elucidatory value. The combination of the two methods of investigation, instead of taking the analysis in one chapter and the curves in another, as in the previous editions, is a marked improvement.

Turning next to the chapter on "Alternate-Current Machines and Transformers," we find that the machines of Zipernowski, Westinghouse, Mordey, and others are now included, and the ingenious method of regulation introduced by Zipernowski is explained. The chapter on "The Elementary Theory of the Alternator" comes next in order, and although slightly enlarged from the previous edition, it cannot be said to do more than touch the fringe of the complex and difficult questions involved. In the present state of knowledge the data for a comprehensive treatment of the subject can scarcely be said to exist, but in future editions we may reasonably expect that it will receive much fuller consideration.

We may remark in passing that if the learned author can give us anything like a good working theory for the design of alternators, especially those with iron in the armature, he will have accomplished a task whose difficulty only those who have tried their hand at it are in a position to estimate.

The chapter on "Transformers" contains an excellent historical summary of the process of development which the induction coil has now undergone, and half-a-dozen of the best-known converters are illustrated and described. We are then introduced to the usual analytical investigation, which we take it is in this connection more than usually inadequate to represent the facts. We should have preferred to see the graphical constructions of Kapp and Blakesley, with such extensions as the ingenuity of the author would no doubt have suggested. The graphical method is not only capable of solving questions relating to transformers which are practically incapable of solution in any other way, but it has also the merit of displaying more fully the *modus operandi* of the several reactions involved. At the same time the student will obtain some insight into the general physical characteristics of the problem from a very excellent *résumé* to be found on pages 493-5. Unhappily, it must be confessed that at present no thoroughly satisfactory treatment of alternating-current problems is even imaginable. The assumption of a purely harmonic function for the current variation can only be justified as a first approximation, and under the actual conditions of practice it is probable that the rise and fall of the current waves is something very different indeed; especially when there is much iron enclosed by the circuit. In an ideal case an alternator intended for transformer service would be so designed as to give a curve of the most efficient shape under normal load. Happily, however, the efficiency of the transformer is in general so high that this refinement is probably quite superfluous. As to the efficiency of modern alternators little or nothing has yet transpired. The question is, however, one of considerable practical importance in view of the gigantic machines of this description which are now being built.

Six chapters are devoted to the electro-motor. This portion has been almost entirely re-written, much new matter has been added, and the mathematical treatment has been revised and curtailed. Upon the whole, and in spite of the skilful and ingenious manner in which many of the problems are dealt with, we do not find this portion of the work altogether satisfactory. Our objection is of a generic character. The subject is handled almost exclusively upon the basis of the laws of maximum efficiency and maximum output, which are ascribed to Jacobi and Siemens. The author is of course aware, and, indeed, he calls attention to the fact, that these are the laws of an ideal motor—a motor in which there are no losses other than those due to the resistance of the conductors, no Foucault currents, no hysteresis, no self-induction, and no mechanical friction. It may be, possibly it is, still useful to retain all that the author has elucidated concerning the behaviour of the ideal motor, but it would, we think, have been better to have incorporated some further account of the characteristics of existing machines, particularly in respect of the points in which they depart from the theoretical standard. As a simple matter of fact the work rendered by an electric motor is *not* represented by the product of the current and the *calculated* E.M.F., the latter being obtained by writing

$$E = \mathfrak{E} - i\,R,$$

where $\mathfrak{E}$ is the E.M.F. of supply, i the current, and R the resistance of the machine. Nor can the true value of E be obtained in any actual case save by the application of a brake-test. We can then write simply

$$E = \frac{W}{i},$$

where W is the power obtained expressed in watts. In a recent number of this journal (*The Electrician*, August 31, 1888, p. 522), Mr. A. T. Snell pointed out the utility of this method, and how by comparing this with the value previously written for E, we might discriminate betwixt the ohmic and the other losses, and so glean valuable information upon the merits of the design.

In fact, we think that a little consideration will show that an attempt to investigate motor problems upon the assumption that the useful work is equivalent to the product of the current and the calculated back E.M.F., is much the same thing as an attempt to find the E.M.F. of a dynamo by dividing the measured horse-power on the pulley (in watts) by the current. We expect that the worthlessness of any but dynamometer tests for motors will soon become an established article of the electrical engineer's creed.

Digitized by Google

Since the theory of motors has been less widely studied than that of the dynamo, we may usefully proceed to a few more detailed criticisms. In the chapter upon the reaction between the armature and the field of the motor the author maintains his earlier views (in opposition to those of Profs. Ayrton and Perry) that the rules governing the construction of dynamos apply almost without change to motors. We take it, however, that either side is partly in the right and partly wrong. For shunt-wound machines of large size we should agree with the author, and for small, series-wound machines with his antagonists. Dr. Thompson very properly remarks that the elimination of eddy currents should be even more carefully attended to in the latter case, since, as was first pointed out by Mr. Mordey, the eddy currents in the armature core are assisted in the motor by the self-induction of its coils, while in a generator these inductions are mutually opposed. He also lays great stress on the fact that "the field-magnets must be made very powerful in proportion to the armature." Some definite illustrations from recent practice would have been useful here, and since none are given we may mention that in one of the best-known machines of modern design, the relative sections of the iron in armature and field is about 1:2 in machines of medium size. In these machines the lead is constant for all loads within the limit of the design, and there is practically no sparking. Taking this proposition as it stands, we find, however, that its consequences are elucidated by the author with his customary thoroughness and cogency. On page 567 we come across a statement which, although perfectly true in itself, should perhaps scarcely find a place under the heading of "General Expressions for Torque and Speed," since it can never apply to the important case of series motors. No doubt "if N be constant, the torque is simply proportional to the current in the armature;" but since N is constant only in case of a shunt motor supplied at constant difference of potential, the utility of the statement as a "general expression" is somewat dubious. The expression for speed in equation (γ) on page 568 might, we think, be made more clear by substituting the value of T, namely, $i_a \frac{CN}{2\pi}$ (where T is the torque, i_a the armature current, and C the number of turns of the conductor on the outside of the armature) the equation is

$$n = \frac{\mathfrak{E}}{CN} - \frac{2\pi T r}{C^2 N^2} \quad . \quad . \quad . \quad . \quad . \quad (\gamma)$$

where $\mathfrak{E}$ is the E.M.F. of supply, and n the speed; substituting the above values of T we get

$$n = \frac{\mathfrak{E}}{CN} - i_a \frac{r}{CN} = \frac{E}{CN},$$

where E is the counter E.M.F. This expression shows clearly that the speed of the motor depends on its own counter E.M.F. and not directly on the E.M.F. of supply, provided N be constant. The author, on the contrary, having apparently confined his attention to the (γ) equation and neglecting the second term, says that if N be constant the speed is proportional to $\mathfrak{E}$. It is true that these statements become practically identical if we are speaking only of a shunt-wound motor, with a low armature resistance, supplied at a constant E.M.F.; but as an expression of a general character the author's version is scarcely accurate.

Special attention should be directed to the mechanical characteristics (pp. 569-75) which serve to show with great distinctness the relations of E.M.F., current, speed and torque, which are not always clearly understood. The conditions of a shunt motor running under constant current might, perhaps, be stated with some additional clearness. The points of minimum and maximum torque should be clearly brought out. The maximum torque will obtain when the value of the product ($N i_a$) is a maximum at a certain critical speed, the latter varying for each motor. *Two* minimum or zero points occur when i_a and N are severally at their maxima—that is to say, first, when the motor is at rest and all the current is practically going through the armature; and, secondly, at its maximum speed, when the armature current is at a minimum.

There is a valuable chapter on the self-government of motors, which at the present moment involves problems almost as difficult as the self-government of the Hibernian race, although we are happy to believe that the former is nearer its realisation than the latter. The application of compound differential winding in the case of constant difference of potential results in a maximum value of N when the motor is running light, and the maximum rate of doing work (not torque) is obtained with a lower value of N. This method, though correct in theory, has some disadvantage in practice, as it involves a relatively heavy machine. We believe that the plan which has hitherto found most favour is to design the motor so that the output is greatest with maximum values of N and T. This involves series-winding and a variable strength of field, which may be attained with a centrifugal governor, cutting in or out some sections of the field windings. A motor of this description, built by Messrs. Immisch, was shown by Prof. Ayrton in his lecture on the Transmission of Energy, before the British Association at Bath (see *Electrician*, Sept. 14, 1888, p. 598); it is also in use in America. But, as the author remarks, this is not a faultless method, since obviously the speed cannot be quite constant. Perhaps for constant potential motors the best practical solution is given by a few series coils acting with the shunt winding. Such a machine is self-starting, and will run at fairly constant speed.

The concluding chapter on Testing Dynamos and Motors is excellent throughout; the chief novelty—and the only one which we have space to mention—is the suggestion (in p. 594) for examining the perfection of the magnetic circuit. The dynamo (or the motor driven as a dynamo) is run upon a suitable external resistance at a gradually increasing speed. The least speed of excitation is, *cæteris paribus*, a measure of the goodness of the magnetic circuit. The theory of this test is further developed in an Appendix, but we may add that in practice care should be taken that the external resistance is made about equal to the normal resistance of the circuit when the machine is taking its full load.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714.

All Communications to be addressed to "The Electrician," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician."

All letters intended for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.

"The Electrician" is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.

SPECIAL NOTICE.

Owing to the increase in the number of pages of "The Electrician," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
„ Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"The Electrician" offers exceptional advantages to Advertisers. **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Trade Advertisements *intended for the current issue must be handed in not later than First Post on Thursday morning.*

Small Prepaid Advertisements *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"The Electrician" Printing and Publishing Company (Limited) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "The Electrician" Electrical Trades' Directory and Handbook. The Directory was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.

THE DIRECTORY for 1889 will SHORTLY BE READY.

1888.

(CONCLUDED.)

Telegraphs.—The traffic of the Post Office Telegraphs during the past year has maintained the steady rise which followed on the reduction of the rate in 1885; and there is now a prospect of not only recovering the loss of revenue consequent upon that reduction, but of meeting expenditure and interest on capital by current receipts, although not, perhaps, of overtaking the arrears which have accumulated from the time of the original purchase.

The following is a comparison of the gross revenue of the Telegraph service for the four quarters ended 1887 and 1888:—

	Mar. 31.	June 30.	Sept. 30.	Dec. 31.	Total.
1888 ...	480,000	480,000	565,000	515,000	...£2,040,000
1887 ...	445,000	465,000	540,000	465,000	...£1,915,000
Increase					£125,000

Partly because of the financial position of the service, but largely also because of the rise in the price of copper, the Department has made none but absolutely necessary extensions during the year, copper being the material which it is proposed in future to employ for all long circuits instead of galvanised iron. A perhaps not wholly regretable consequence of this check to the multiplication of wires has been the perfecting and extending the use of multiplex telegraph apparatus so as to force the constantly-increasing traffic through the existing system of conductors; and it is satisfactory to learn that the results foreshadowed by Mr. Preece, and noticed in our last year's review, have been fully borne out by the practical experience of 1888.

Digitized by Google

CABLES.—Perhaps the most notable event of the year has been the nationalisation of the property of the SUBMARINE TELEGRAPH COMPANY, whose exclusive rights between the coasts of England, France, and Belgium are just on the point of extinction. We say nationalisation because it is not yet publicly known to which nation or nations conjointly the old company's cables have been transferred. This much, however, is clear, that the SUBMARINE TELEGRAPH COMPANY will cease operations at the end of next March, and that its cables will henceforward be worked under a friendly agreement by the several nations interested. Obviously the maintenance of these cables and the laying of fresh ones will fall upon the shoulders of the British Government, who will have a commanding influence, therefore, on their management and the rates which are to prevail over them. Already steps have been taken to introduce fast speed working over these lines connecting England with the Continent of Europe; and although the tariffs will not be lowered to any considerable extent in the first instance, the transmission of messages will be accelerated, with much advantage to the public.

Of the other submarine cables immediately connected with these shores we may note with satisfaction the cessation of hostilities between the several Atlantic Companies on the 1st of September last, when a joint-purse agreement was entered upon, based on a tariff of one shilling per word—just double the charge at which the companies had been ruinously competing for about two years previously. It is understood that the traffic has not materially fallen off under this increased rate, and that unless some fresh competitor enter the field the existing companies now in possession of the Atlantic may hope soon to recover a little of that financial prosperity to which their enterprise and perseverance entitle them; but it may still be doubted whether even a shilling tariff can be made remunerative over cables of such enormous length.

A cable has been projected, or rather threatened, connecting the West of Canada with the Australasian Colonies. The scheme, however, is as hazardous as it is—for the present, at all events—superfluous. If ever such an alternative route to the far East becomes necessary it will probably be undertaken by competent hands, not by the inexperienced and somewhat visionary advocates who at present have the scheme under their special patronage.

Of far greater practical import is the cable now about to be laid under the auspices of the EASTERN TELEGRAPH COMPANY on the West Coast of Africa, from Loando to the Cape. A girdle of electrical communication will then almost encircle the Dark Continent, and a choice of routes to one of England's most important naval stations will be established, as well as to commercial regions in the interior, the development of which will be greatly assisted by this improved means of communication.

It is understood that the section from Loando to Mossamedes, 700 miles in length, is being manufactured by the Silvertown Company, and that from Mossamedes to the Cape, 1,500 miles, by the TELEGRAPH CONSTRUCTION COMPANY. In this relation we may mention that the TELEGRAPH MANUFACTURING COMPANY, at their Helsby Works, have this year turned out nearly 7,500 miles of insulated wire, and upwards of 1,000 railway telegraph instruments, besides a considerable number for the Post Office.

Active preparations are being made by the EASTERN EXTENSION TELEGRAPH COMPANY for laying a third cable from Java to Australia, avoiding the volcanic route occupied by the two existing cables, and landing much further south on the West Australian coast. The length of this new cable, which is being manufactured by the TELEGRAPH CONSTRUCTION COMPANY, will be about 1,000 miles.

TELEPHONES.—Notwithstanding several incidents of an unsettling character which have occurred during the year, the telephone companies of England and Scotland, and to a less extent also of Ireland, have made very substantial progress, extending their trunk lines over considerable areas of the provinces, and completing their ramifications in the town districts. Never before, perhaps, have the companies shown such activity, or such a determination to firmly establish their hold on public confidence in the face of threatened trials. An attempt has even been made to bring about an amalgamation, and so to create a practically united and unassailable monopoly. As yet, however, the project seems to hang fire, whether owing to internal differences among the parties, or to legal difficulties raised by the POSTMASTER-GENERAL is not precisely known. One thing only is taken for granted, namely, that Mr. RAIKES regards these telephonic operations with apprehension and disfavour. In official quarters this is strenuously denied; but, on the other side, his public utterances are quoted as showing that he contemplates with some satisfaction the prospect of being able to dish the companies when their patents expire. A fairer interpretation perhaps would be that he means to negotiate with them in the interests of the public at large, and on more equal terms, when he is free to do so. Meanwhile, it must be confessed that no assistance from the Government has been given to the UNITED TELEPHONE COMPANY in promoting their long-delayed Bill for putting the question of overhead wires on a more intelligible legal basis. That Bill had to be again withdrawn early in the Session, owing to the action of local authorities, whose threatened opposition the Government took no pains to overcome. One result of this has been the abnormal activity to which we have made reference above, the companies making haste to cover the ground wherever the field shows promise of a future harvest. Happily the legal troubles of the telephone have begun and ended here, for in every one of its suits against intending competitors it has secured an easy triumph, its position being in no way disturbed in this country by the varying decisions respecting it in the High Courts of America.

Although not yet connected with the trunk wires of the provincial companies, the UNITED TELEPHONE COMPANY has reason to be satisfied with the patronage it has secured in the City and the suburban districts. A few figures will illustrate the progress made in the past twelve or fifteen months. In the month of September, 1887, the number of messages passed through the London Exchanges were at the rate of twenty-one million per annum. In the corresponding month of 1888 the rate amounted to twenty-two millions; whilst for the months of December in the corresponding years the messages were at the rate of twenty-five and thirty millions respectively. The main trunk line which this company is erecting to the north already covers about half the distance between London and Birmingham, and the ground is being surveyed for the erection of a similar line telephonically connecting the Metropolis with Bristol and South Wales

The last named district is already locally served by the WESTERN COUNTIES AND SOUTH WALES COMPANY, the extent of whose trunk line operations between such places as Bath, Gloucester, Newport, Cardiff, Swansea, Pontypridd, &c., may be judged from the fact that in the month of November last 30,028 conversations were recorded over these inter urban lines. The LANCASHIRE AND CHESHIRE TELEPHONE EXCHANGE COMPANY, which serves the district of which Liverpool and Birkenhead may be said to be the centre, has increased its trunk wire communication to 2,580 miles, the total mileage of the company's system at the end of September last being 8,930 miles. The revenue from the trunk wires and call offices of this company has just doubled in the last three years—that is to say, from £4,000 in 1885, it has reached £8,000 in 1888.

Digitized by Google

There are 120 public call offices in this district, and between 40 and 50 towns connected by trunk wires. The charge for a conversation of three minutes' duration between persons in the same town is threepence; sixpence between persons in different towns situated in the Lancashire and Cheshire district; and one shilling when extended to the Yorkshire district of the National Telephone Company's system. Already these two companies are connected at many points, their respective subscribers being able to converse over the whole area covered by both. The National Telephone Company is the largest of the provincial companies, its district including a great part of Scotland, a portion of Ireland, the county of Yorkshire, and the Midland Counties. It possesses 126 exchanges—22 more than it had last year—and has established over 50 additional call offices, the total number being now 246. Its exchange lines number 8,607, and its private lines 1,331. A much smaller area is covered by the Northern District Telephone Company, but here again the same increasing activity is observable, its exchange subscribers having increased from 576 in 1887 to 805 in 1888, and its calls from 2,650 to 3,420 per day. The wire mileage belonging to this company is 2,660 miles, 1,430 of which are trunk lines, 800 for exchanges (18 in number), and 430 for private lines. It is estimated that the revenues of the three principal telephone companies referred to above for the year 1888 will be as follows:—The United £92,386, an increase of £2,431 on the previous year's receipts; the National £78,354, an increase of £10,902; the Cheshire £71,420, an increase of £5,626.

Coast Telegraphs.—We note with satisfaction the great progress made during the past year in bringing to an issue the important question of electrical coast defences. That part of the subject which relates to the safety of our mercantile marine in dangerous weather, and in case of shipwreck, is being experimentally dealt with at one or two points on the coast, and it is believed with encouraging results. When it is remembered how large is the proportion of disasters occurring to British vessels within about ten miles of the British coast, the importance of being able to command assistance from shore by telegraph or telephone established at suitably chosen light-vessels or light-houses beomes self-evident. Of, perhaps, equal concern to the nation is the protection of our shipping and ports from hostile incursions. The scheme which finds most favour, and which we understand originated with Mr. F. E. Baines, C.B., of the Post Office Telegraph Service, proposes to carry round the British Isles a line of telegraph following the coastguard path and connected at convenient points with the Postal Telegraph inland system. Proposals of this kind, which would admirably supplement the duties of the lightships' electrical systems, are, we believe, now before the Defence Committee, and are in a fair way for being, at all events partially, adopted.

Copper.—The gigantic operations of the Société des Métaux in copper have had a very disturbing effect upon the market. At the end of 1887 copper was quoted at £42 per ton; it now stands at £77. 12s., and has touched £80 during the year. The syndicate commenced operations by effecting a purchase of 42,000 tons of copper, representing practically the whole available stock, at a cost of nearly two millions sterling. It also entered into contracts to take the produce of copper mines all over the world to the extent of between 60,000 and 70,000 tons per annum, each mining company undertaking to limit its output to the average of the preceding three years. Of course this has had the effect of stimulating the activity of those producers who have continued to stand outside the ring, and many new or abandoned mines have been opened up. As the net result we find that the total imports of the metal during the first eleven months of the year amounted to 246,993 tons, or an increase of 68,918 on the previous year. When to this it is added that the actual consumption has necessarily been restricted by the rise in price, and that a lot of old metal has found its way into the market, it is evident that the stock in the hands of the syndicate at the present time must be huge. Rumour puts it as high as 150,000 tons. What will be the final outcome of this state of things it is impossible to say, but we see no immediate likelihood of a fall in price.

ELECTRICAL AIDS TO THE DRAMA.

The following interesting article, which we reprint from the *Scientific American*, will initiate our readers into some of the electrical devices which are employed with such striking effects upon the stage. We may add that several of the methods here described were used at the Lyceum during the performances of "Faust":—

The electrical sun is a big ground glass disc, with a voltaic arc lamp behind it of about 2,000 candle-power, connected with the street circuit. It shows through a hole cut into a drop curtain, and is set firmly in a frame covered with coloured gauze to represent the various hues with which it tinctures the atmosphere and the colours it projects upon the clouds during ascension and declination. One of the best effects yet had with this artificial sun is in Meyerbeer's "The Prophet," Act III., Scene I. The Anabaptists are encamped in a Westphalian forest near by a frozen lake that loses itself in the mist gathered at the horizon (also an electrical effect). The day is going down in the west with the sun. The fierce arc lights are moderated through a golden gauze, then softened by the ground glass outside.

As the sun is let down behind the paper mountains the purple and red gauze is pushed up over his face, and the lower clouds, now changed from cumulus to stratus, take on those horizontal lines of colour we know so well. "Tannhauser," Act III., Scene II., shows the mellow glowing of twilight, the masterful incandescent light, hooded in pale yellow, controlling the haze so well that in the expanse of mimic sky there is not a tint to dispel the illusion. The evening star in the south-west twinkles clearly like the ruby Mars. Wolfram, the minstrel knight, seems justified in his apostrophe:—

> "I look on thee, O star in heaven the fairest,
> Thy clear cut beam thro' trackless space thou bearest,
> The hour of darkness is by thee made bright,
> Thou lead'st us upward with kindly light."

This star consists of a single 16 candle-power incandescent light, connected with the street circuit, and affixed to a metal frame set in the drop curtain, only the star itself, with a covering of red gelatine tinctured with blue, showing through. In the duel scene in Gounod's "Faust," Act IV., Scene VII., will be found a striking electrical effect. As will be remembered, the soldier Valentine, brother to Marguerite, fights with Faust, the student and Marguerite's lover. As he is unfamiliar with the use of the sword, the Devil, in the guise of Mephistopheles, stands by, sword drawn, to aid him, interposing the weapon when Valentine makes too fiercely at the student. Heretofore, though there was a clash of swords, there was not here anything to indicate the possession of supernatural powers by Mephistopheles. The electric wires are connected with Valentine and Faust. The poles of the battery are connected under the stage with copper plates sunk into the flooring where the duel takes place. Copper nails driven, one into a shoe of Valentine, the other in that of Faust, connect up with the floor plates whenever they respectively stand upon them, and wires running up the legs and body of each and then down their several sleeves end in a small plug. So, when they draw their swords, they have but to insert these plugs into the holes sunk into their hilts and they are connected up with the electrical storage battery in the wings, Valentine representing the positive pole, and Faust the negative.

Every time Mephistopheles interposes his sword and strikes up the contending weapons, which are then brought in contact, the sparks fly furiously, and there are those weird, crackling, sizzling sounds heard in the lightning as well. When Valentine gets his death wound, he throws out the plug connecting his sword with the battery, by a simple turn of the thumb, and, as he falls, his sword flies from his hand with nothing to show the presence of any electrical connection.

Digitized by Google

Everyone familiar with the charming music drama by Wagner, the "Ring of the Nibelung," will recall that impressive scene in the first act of Siegfried, where the stout lad Seigfried welds together the broken pieces of his dead father's sword which have been left him by his mother Sieglinda. The scene represents a cave in the rocks with openings into the forest. It is a smithy's forge, with fire, chimney, and bellows. The point of this scene lies in the prodigious strength of the lad Siegfried, who, because of it, succeeds where Mime, the smithy, has failed, and welds the terrible sword that is to kill the dragon who guards the treasure. The anvil upon which the lad strikes is connected by concealed wires with the storage battery, the positive plate being a corrugated piece of cast iron 6½in. by 12in., the negative pieces of iron wire three-sixteenths inch diameter and 12in. long, bowed upward at their centre and placed above and free of the corrugations below them. The current required being of 15 amperes, if the negative wire should rest upon the positive plate, a dead short circuit would be formed, and all metal connection with the battery would be fused; but bowed as they are, there is but a momentary short circuit at each stroke of the hammer, when the springy wires are forced down upon the under plate, producing only a shower of sparks, as if from the great force of the blows struck. At last, when the sword is completed, and a firm handle upon the hilt, he determines to test its temper, and raising it aloft brings it down with what seems a tremendous blow upon the anvil, which falls into two parts, as if cleft in twain, the sparks following the sword down to the ground. In reality he strikes a spring, which lets one-half the anvil fall, its under and outer side, as will be seen, having the corner cut off for the purpose and causing momentary short-circuiting.

A very pretty electrical effect is had in the garden scene in "Faust," Act III., Scene VI. Siebel, the would-be lover of Marguerite, advances to a bed of tulips, some red, some white, and some gold, to pluck a nosegay that he would leave upon her window to speak for him. Concealed in the corolla of each flower, or, rather, disguised as stamens and anthers, are two tiny incandescent lamps (15 volts each), the whorl of petals fresh and sparkling as when we see them fed with sunlight. Now, the demon Mephistopheles had long before warned Siebel—

"Every flower that you touch
Shall rot and shall wither."

Unheeding, Siebel picks a golden tulip, which shines yet as he lifts it up to him (the fine wire carrying the electrical current that keeps the bulbs in the flower aglow trailing after it, unseen amid the foliage). No sooner does he examine it, when, lo! Mephistopheles, partly concealed, raises his hand, the current from that single flame is cut off, and it grows dull and withers perceptibly. Siebel says—

"What, faded! Ah me!
Thus the Sorcerer foretold at the fair:
That, should I touch a blooming flower,
It shall wither.
But my hand in holy water I'll bathe—
See, now, will they wither?"

Here he plucks a red tulip, a white and a golden one, holding them up triumphantly, a rich, mellow glow in each (the electrical current following upward along the fine wire and the little bulbs yet lighted), for Mephistopheles may not raise his hand against the power of what has been blessed. Then he changes hands, and, like a flash, they fade, beaming with light again when he, remembering it was the other hand that touched the holy water, hands them back. (The operator, watching the scene, switches on or off as required.)

In the last act of Siegfried the wanderer (Wotan) is standing at the foot of a high cliff, with a deal of thunder and lightning overhead. He is armed with a great spear, steel-tipped and pronged, with the wood of it studded with steel. It is supposed to contain the sacred though unseen fire, and heretofore, until the present application of electricity, there was no evidence of it, save Wotan's word. He, as guardian of the rocks, is pacing up and down, with the spear in his hand. Siegfried comes seeking Brynhilda's rock. As Siegfried approaches he draws his sword, dealing a heavy blow against the spear of Wotan, while at the same moment a man in the wings turns an electric switch. The spear parts and from its shattered ends flames, like forked tongues, leap out. A lamp of 30 volts intensity is hidden in the spear; the core wrapped with heavy brown paper for insulation, with a mass of secondary cotton stuffed about the carbons at the point where the spear is to part. Then come thunder and lightning and black, rolling clouds, the last two projected upon the mimic sky by a stereopticon in the wings. The lightning and the clouds are scratched and painted on small bits of glass, before projection being greatly magnified by lensing, with a powerful voltaic arc electric light behind the condenser throwing them with wonderful precision and naturalness, the clouds rolling across an apparently immense expanse of sky, as the operator revolves the discs one over the other, and the forked lightning seeming to shoot across the heavens.

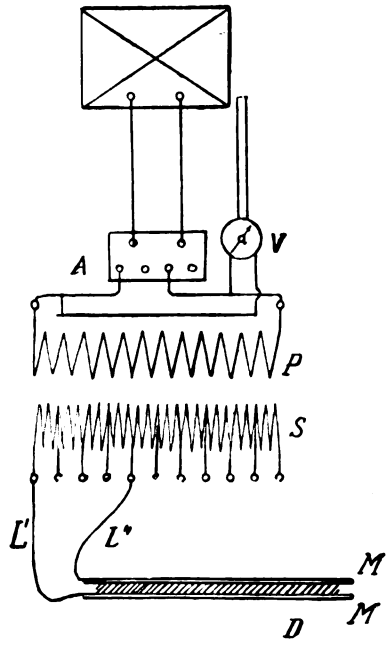
The realistic fire clouds and flames in the last act of the "Prophet," where the latter, learning he is betrayed, orders the firing of the Palace of Munster, are done by concentrating the arc light upon coloured gelatine, using first yellow for fumes, then yellow and white, then yellow and red, red and white, red and black. The snowstorm in "the Prophet" is made by forcing the light through white scratches on black glass. The sandstorm in the last act of the "Queen of Sheba" is done with yellow and black and pink gelatine before the light, and the rain by parallel scratches on a black surface, the arc light being dimmed and set aglow alternately, and the glass turned this way and that, so that the parallelism of the drops shall follow a supposititious changing of the direction of the wind.

The firefly is another fine effect, devised by the same hand as the others, and recently used at the Broadway Theatre, in the play of "The Kaffir Diamond." Tiny 15-volt incandescent bulbs were affixed to the weeds and rushes in a swamp, each bulb getting its life from a fine wire connected to an electrical accumulator in the wings. The operator in his hiding place, by pressing upon the knobs of his key-board alternately, lighting up one and then another, could make a single firefly appear to be darting hither and thither; then there would be two of them, a half-dozen, a score, or, pressing upon all, twenty-eight.

The artificial rainbow is made by the interposition of two triangular glass prisms, one elevated slightly over the other, before an electrical reflector, the bases and faces and lateral edges carefully adjusted with regard the one prism to the other. The electrical sun, set opposite to the point where the rainbow is to appear, is made, the better to aid the illusion, to shine into a mass of cloud, the rainbow seemingly only the reflection, refraction, and disintegration of sun rays into the various colours of the prismatic spectrum, the influence of the rain drops. So ingenious is the work that there is made to appear, as in nature, two arches, the primary with its inner circle of red, and the secondary with red along the inner.

A 10,000-VOLT TRANSFORMER FOR TESTING INSULATION RESISTANCE.

The ordinary tests of insulation, consisting only of a measurement of the insulation resistance, under the comparatively low



E.M.Fs. usually available, afford very little guarantee, especially in the case of electric light cables for the working strength of the insulation. It therefore seems very desirable to take advantage of the facilities afforded by alternating-currents to test such cables under much higher E.M.F.'s than they will be subjected to in practice.

At the "Menier" Electric Cable Works in Paris-Grenelle an alternating-current transformer, made by Messrs. Ganz and Co., of Budapest, has been used since March, 1888, for the purpose of testing cable insulation, or any other dielectric resistance. This transformer is constructed with a primary coil, P, for 100 volts and 70 amperes, and a secondary, S (*see* Fig.), for 10,000 volts and 0·07 amperes, the ratio of transformation being 1·100.

Digitized by Google

The secondary coil is divided into ten divisions, the ends of which are led to metal contact pieces with conical holes. By means of two plugs and two flexible leads L'L", the dielectric to be tested can be subjected to a difference of potential of from 1,000 up to 10,000 volts, and its behaviour observed.

In the primary circuit there is, as well as the generator, a double-pole switch, A, in order to cut off the primary circuit entirely, before altering the secondary difference of potential by shifting plugs. A Cardew voltmeter is used for the control of the primary tension.

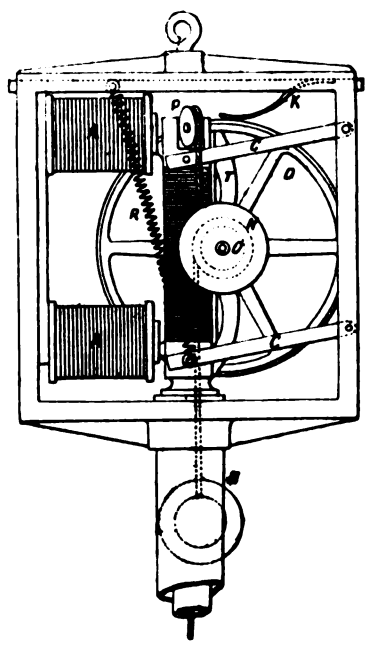
Concerning the construction of the transformer it may be mentioned that the primary and secondary coils, as well as the divisions of the secondary, are carefully insulated from one another with ebonite. The metal pieces forming the terminals of the secondary divisions are mounted on high ebonite supports, the metal plugs being also furnished with long handles of the same material.

The transformer, together with the terminals, is mounted on a strong base-board, on which there is also a double pole-switch with porcelain base and handle.

This method of testing the insulation of cables obviously affords a far better guarantee for their safe working in actual use than that of testing by measuring the insulation resistance with a comparatively low E.M.F., for it may happen that a layer of insulation which shows with only a few hundred volts an infinitely good resistance could be broken through by a few thousand volts.

THE BURGIN ARC LAMP.*

The two chief points in the mechanism of this ingenious lamp are the thick wire electro-magnet A, and the fine wire armature y. The



coils of A and y are wound so that the adjacent poles are of the same sign. The upper carbon-holder is suspended by means of a cord which passes round the pulley N, over the pulley P, and down the interior of the armature B, which is hollow throughout. A second cord, attached at one end to the ring M, and then wound round a drum which is fixed to the shaft O, serves to hoist up the upper carbon-holder when the carbons are burnt. When the current is switched on the armature is attracted by the electro-magnet. This attraction causes the arms c to move to the shaft O to lift; the arc is thus struck, and at the same moment the spring K is pressed against the wheel D. As the carbons are consumed the resistance of the arc increases, and more and more current goes through the shunt, until at last the repulsion between the poles of the armature and the magnet becomes great enough to force the armature slightly down. The wheel D is thus freed from the brake K, and the upper carbon-holder feeds down under the action of gravity. The moment this takes place, the whole system enters into a state of unstable equilibrium, resulting from the combined action of the brake K and the magnetic forces on the one hand, and of the spring R and the weight of the carbon-holder on the other. Owing to this condition of things the positive carbon feeds down slowly and continuously, and a satisfactorily steady arc is obtained.

* Translated from M. Hippolyte Fontaine's "Eclairage à l'Electricité," by kind permission of the author.

INCANDESCENT LAMPS: CANDLE-POWER AND CURRENT.

In the *Centralblatt für Elektrotechnik* Herr K. F. Slotte publishes a series of investigations to show that the candle-power of a glow lamp varies directly as the fourth power of the excess of current over that at which the lamp first begins to emit visible rays; that is

$$l = k\,(c - c_0)^4,$$

where k is a constant differing for every lamp, l the candle-power at current c, and c_0 the current at which visible rays first begin.

The following (shortened) table shows the results obtained with an 8 candle-power Edison lamp :—

EDISON LAMP, 8 candle-power. $k^{\frac{1}{4}} = 2{\cdot}707$, $c_0 = {\cdot}29$.

c	$l^{\frac{1}{4}}$ Calculated.	l. Observed.
·525	·64	·68
·610	·87	·87
·732	1·20	1·20
·842	1·49	1·48
—	—	1·68 = 8 c.-p (normal)
·990	1·89	1·91
1·23	2·54	2·54
1·29	2·71	2·66
1·32	2·79	2·66 = 60·1 c.-p.

Similar close agreement between the observed and calculated columns obtains also in the case of two Bernstein lamps, two Siemens, a Woodhouse and Rawson, and a Cruto. It will be noticed that the observed candle-power drops a little behind the calculated when the lamp is very much overrun. This occurs also in a 20 candle-power Bernstein, for which the author gives observations up to 480 candle-power, at which the lamp broke down, but up to 280 candle-power the agreement shown between the theory and experience is almost absolute.

ELECTRICAL COAL-CUTTING MACHINES.

The following is an extract from the Address of the President of the North of England Institute of Mining and Mechanical Engineers, delivered 8th December, 1888 :—"As bearing on accidents, coal-cutting by machinery is an important question, because of its effect on the number of men at the face of the workings. An engineering friend recently urged me to see Messrs. Bower and Co.'s electrical coal-cutting machine and electrical transmitters, and although your past president, Mr. John Daglish, in 1886 pointed out in his address several objections to electrical transmission, many of these have been surmounted, and others no doubt will be. I have therefore inspected the machinery, and have much pleasure in giving the following description, as a striking instance of the applicability of electric power in mines and collieries, and of its utility when the motor is to be moved about. This electric coal-cutting machinery is now being introduced by Messrs. W. T. Goolden and Co., of London, as licensees under the patents of Messrs. Bower, Blackburn and Mori, with further subsidiary patents. Messrs. Bower had for some years been experimenting on the use of coal-cutting machinery and had arrived at last at a form of machine which gave most satisfactory results, except in so far that, unless near the source of power, great difficulty was experienced in obtaining the necessary motive power. At last electricity was tried, and although considerable modifications have had to be made in the original method of application, by attention to every detail, very satisfactory results are now obtainable. This machine is only now being put into the market, as the makers have been anxious to discover every fault and overcome all difficulties practically before bringing it out seriously. The original machine was started in May, 1887, and is still running, doing very good work; although since then the machines have been completely remodelled and greatly strengthened. The machine consists of a frame travelling on wheels, carrying a specially designed electric motor, driving a shaft which carries the cutter attached by bolts to a coupling. This cutter consists of a bar carrying a series of star-shaped cutters, specially formed. The whole motor, and the shaft carrying the cutter bar, can be rotated in a horizontal plane, for the purpose of bringing the cutter in and out of the coal. The cutter is revolved by the electric motor at about 600 revolutions per minute, and the motor develops six to nine actual horse-power according to the hardness of the seam.

"The method of operating is thus. The motor is started, the turn-table is rotated by the worm wheel till the cutter has swept through a right angle, and is then 3 feet 6 inches deep in the coal. It is then drawn along the face by a winch, under or over-cutting the coal to that depth. The form of the cutter obviates the great

Digitized by Google

difficulty usually met with in coal-cutters, viz., the jambing of the cutter by the falling coal, as in this case the cutter is always against the solid coal, and has never been known to be stopped when running by falling coal. The speed of cutting varies with the seam. These cutters have actually effected 45 yards per hour, including all stoppages, to put up props, &c., and in actual cutting time 30 yards have been cut in 36 minutes in hard dirt with pyrites and ironstone lumps. The advantages of the machine are obvious, the cutting can be carried on in any seam of dirt, thus saving coal. Only about 4in. of coal is removed. The coal is cleaner, and in larger pieces. A smaller length of face is required for a given output of coal, thus reducing bye-work, &c. The power is brought from a dynamo at the surface by two thin cables, whose position can be altered in a few minutes, as they can be rolled up and run out and hung on hooks like a piece of cord.

"Messrs. Bower's cost of holing by hand is about four times per yard more than by the machine. The difference in percentage of small is 10 per cent. in favour of the machine.

"The dynamo producing the electric current is situate preferably at the surface, and the power is led down the shaft by two small cables. Where wet or foul air is met with the lead-sheathed cables, manufactured by Messrs. J. Fowler and Co. (Limited), of Leeds, have proved very useful, and give very satisfactory results. The cables are then led along the road, either on insulators or fixed on a wood casing to the roof, or put on the floor. The cable in use at the actual face is a double insulated cable, both wires in one covering, being more convenient for handling. This is attached at any point of the main cable by screw connectors. The actual average engine-power required at the surface will be from 10 to 20 horse-power, according to circumstances, but it is well to run the dynamo from an engine capable of supplying, when necessary, considerably more, and the motor will then develop at times, for short intervals, more than three times its nominal power, enabling it to get through very hard pieces of stone or pyrites which occur in most seams.

"The machines are very strongly built, and designed with a view to being handled by non-technical persons, and all wire on the machine is enclosed in metal cases to avoid mechanical damage, and where necessary the whole of the revolving armature, and collector and brushes are enclosed in gas-tight casings. In addition to the original machine working at Messrs. Bower's collieries, these gentlemen have recently put down two more sets, and the machinery will be under trial at the pits of Messrs. H. Briggs, Son and Co., Normanton, and Messrs. Winn, Nostell, the latter part of this month.

"A new machine is now being worked out, which, employing the same principle of cutting, is adapted for the cutting of headings, either circular, or square, or rectangular."

PROPOSED ELECTRICAL EXHIBITION IN BIRMINGHAM.

We understand it is proposed to hold, towards the close of next summer, in Bingley Hall, a comprehensive exhibition on "popular" lines of electric lighting and electrical apparatus, assisted by industrial exhibits. The present expectation is that the exhibition will be opened about the second week in August, and will remain open during September and October. The main purpose of the exhibition will, of course, be to advance the application of the electric light, by illustrating its working and capabilities in a simple and effective way; but there can be no doubt that the enterprise is capable of being made a great centre of attraction. For example, it is proposed to illustrate the application of the electric light to coal-mines by constructing a miniature coal-pit in the hall. This task has been placed in the hands of an experienced colliery manager, and it is intended to make the imitation perfect in all material respects. There will also be band competitions and other extraneous attractions. In the electrical department of the exhibition the appliances and machinery shown will include dynamos, motors, alternate-current transformers, accumulators, and primary batteries, arc and incandescent lamps, carbons, insulated cables and wires, shades, fittings, &c. There will also be telegraph and telephone apparatus, phonographs, electric bells, and a complete display of electric lighting. Electrical motive power will be used for all working exhibits, and will be applied to all possible industrial purposes, including electric welding, smelting, electrotyping, &c. There will be an electric fountain. The industrial section will be extremely comprehensive, including steam, gas, and petroleum engines and boilers. The Executive Committee can be communicated with as to further particulars at the County Chambers, Corporation-street. We believe an effort is being made to procure the services of the Prince of Wales for the opening ceremony. The net profits of the exhibition are to be divided between the Queen's, General, and Jaffray Suburban Hospitals.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *December 29th*, 1888.

In my last letter I made a brief reference to the earnings and dividends of the Western Union Telegraph Company and the American Bell Telephone Company, the figures proving that both corporations were in excellent financial condition; and it may, perhaps, be worth while to supplement the figures by others which go to show how large is the number of those who are interested as stockholders in these corporations. The general idea is that each of them is a gigantic monopoly, operated for the sole benefit of one or two men. It is curious to observe, therefore, that the Western Union Company has no fewer than 32,000 stockholders, and the American Bell Telephone Company about 1,800. Monopolies which are split up in the hands of nearly 35,000 stockholders would hardly seem to deserve the opprobrious name; and the fact reminds us that in talking of monopolies we must get our ideas adjusted to nineteenth century conditions, under which the owners of a property to which the name of monopoly may be applied number by the thousand, and are, in a word, as numerous as the *employés* of the concern. Incidentally, it may be remarked that a company with as many as 32,000 stockholders on its books must have no small amount of ledger work on that account.

Speaking of the position of the Western Union Company with regard to the public reminds me of the figures which Mr. W. B. Somerville, of that company, connected with the Associated Press, has recently given, as representing the amount of work done for the newspapers. It is very often argued that the telegraph, after all, is not a universal convenience in the way that the postal service is; and here this is taken as one of the reasons why the Government should not have control of the telegraphs. There is some warrant for this view of the case, but at the same time it is to be remembered that through the newspapers the telegraph does become a public convenience and necessity of the first order. In America, as in England, the newspapers are very largely made up of telegraphic despatches, deprived of which the papers would lose much of their interest and value. It is remarkable how, when there is an interruption of cable or telegraphic service, and the newspapers are limited to local news, the horizon closes in upon one, and life seems to lose half its expansiveness and the broad human interest that gives it its charm to a modern. The appreciation of the American newspapers of the worth of telegraphic news is shown in Mr. Somerville's statement that the American newspaper press this last year took about 184,000,000 words of special matter, while the Associated Press sent 327,000,000 more words over its wires. This does not exhaust the figures, however, as there are other press agencies at work in this field. A newspaper has been known to have received 35,000 words of telegraphic matter in a single night, and one of the Western papers is said to have paid over $100,000 for one year's despatches. It may be noted that this matter is almost wholly of the class known as "news"—that is to say, it does not include, as it would in England, frequent and copious reports of political meetings, with Mr. Gladstone or Lord Salisbury at full length. While as a people we are credited with an immense appreciation of oratory, it is a remarkable fact that one very rarely sees a political speech reported in its entirety. Whether this implies a lack of merit in the speeches or an actual distaste for Parliamentary eloquence on the part of the people I will let your readers conjecture. Mr. Somerville, in regard to the cheapness of the service and the encouragement thus given the papers to use the wires, says that the general average rate per word over the country is only from ⅛ to ¼ per cent. per word. It is, of course, this cheapness which has stimulated the growth of the system, for less than fifteen years ago the whole amount of special telegraphic matter taken by American newspapers was only 30 million words.

I made brief reference last week to the movement which was on foot, and the plans which it is understood have practically been

Digitized by Google

consummated, for the combination of all the parent Edison interests in one grand corporation. The capital of the new company is stated at $12,000,000, and Mr. H. Villard, at the head of a number of German capitalists, will put the thing through. The matter attracts a great deal of interest and attention in electrical circles, and is generally regarded as a good sign of the confidence that is now felt in the stability of electric lighting enterprises. There has been a belief in some quarters that the scheme would be extended so as to include the Westinghouse interests in the arrangement, but so far no definite plan of the kind has been discovered; on the other hand, it has been strongly repudiated by both parties.

With regard to the combination of conflicting interests, the *Western Electrician* takes occasion, in a recent issue, to make extended editorial comment on a passage in one of my letters in which I spoke of the rupture between the Westinghouse and Thomson-Houston Companies. In respect to the wider combination, to effect which strong efforts have certainly been made, the paper in question says: "From all present indications the formation of such a trust, which has from the beginning seemed to many impracticable and improbable, is relegated still further to the future, if, indeed, it is ever to materialise." Occasion is taken at the same time to point out that a more practicable plan would be a working arrangement between different manufacturing companies by which they would agree not to sell arc or incandescent apparatus below a certain price per light, and not to intrude into territory already occupied by another company. This is a good suggestion, and if it could be carried out would undoubtedly, in a great many respects, tend to improve and strengthen the business. The trouble is, of course, that through the weakness of human nature, and the outcropping of original depravity, it is generally found pretty hard to get all the parties to live up to their agreement. Our railroads, for example, are always making new deals as to traffic, and then complaining that each other is cutting rates; and it is to be feared that a little similar experience might be had in the electric light field. Then, again, where a company has gone into a town and established a lighting system, and got it upon a good paying basis with local capital, it does seem unfair that another company should come along and break the business up, simply for the sake of getting a foothold. But the difficulty that arises here under a territorial agreement is to determine when that territory has really been developed to its fullest extent. I know of several instances where, to all appearances, the field was pretty well occupied, and the company in possession was doing a good steady business. Another company, enterprising and bustling, comes along, and starts a second local lighting system, and the result is that inside of a year or two the business in the same place has been increased 300 or 400 per cent., and both plants are doing well. On the other hand, there are cases not far to seek where the incursion of a second company has been disastrous to all concerned, so that capital has been rendered timid with regard to this new field for investment. Although it is hard to tell when a town or city has all the electric lights it can find room for, it would always be safe to say that when the competing companies got down to the point where they sold their lights for less than it cost to give the service they had reached a point at which they had better not do business. I do not know whether this question has come up at all in England yet, but here, in America, it has very often been a vital one.

Owing to the large use of copper in electrical industries the course of the copper market is watched with a great deal of anxiety. Of late there has been some hope that prices would fall, and that the French Syndicate which has been manipulating the market would go to pieces. The delay in announcing the revised contract between the syndicate and our American copper companies led to the belief that the whole scheme might fall through, and that the market would settle back to its former condition. It now appears, however, that under the new arrangement there will be little hope for the consumer, and that in all probability prices may be screwed up another peg or two. It is said that under the new arrangement the companies will have a fixed net price for their copper on delivery, and will not have to wait for its sale in order to get a share in the profits. By this arrangement, it is said, the great Calumet, Hecla, and Tamarack Mines will realise a profit of no less than 4d. per pound on their product.

Old as the primary battery is, and vast as has been the work done in connection with it, there seems to be plenty of room for experiment and improvement. One of the recent departures made in this field worthy of note is that of Messrs. I. L. Roberts and H. L. Brevoort, of this city. Mr. Roberts has been an indefatigable investigator for a great many years, and has produced a number of interesting and useful types. In the present instance he and his associate went to work with the intention of obtaining a partition between the two liquids in a battery, which, while having electrolytic properties, should be non-porous; so that, whether the battery was on open circuit or closed, there would be no intermingling of the liquids on either side of the partition, and yet, when the circuit was closed, the battery would give its current freely, chemical action taking place through the partition. Their experiments in this direction have been going on for at least two or three years, and large varieties of materials have been tried. In the latest and more perfect forms of their battery the inventors employ mineral substances of a gelatinous nature. Thus, for example, they use the gelatinous silicate of soda, with which they impregnate the ordinary porous cup. Under these conditions the partition is practically impervious to liquids; yet, at the same time, serves the purpose for electrolytic action, and undergoes such changes as are necessary to the transmission of electric force or current. As the inventors put it, they have in their partition combined in one substance the solid properties of a porous earthenware cup and the electrolytic properties of the liquids, so that they have made the electrolytes solid and the partition electrolytic. The results obtained with this form of battery are said to be very satisfactory, so that they get a much larger proportion of the theoretical energy of the zinc, as current for working in the external circuit, due to the absence of local action, even when the cells remain idle for long periods of time. This would appear to be a promising line of work, and it will be interesting to have from Mr. Roberts at some future time a fuller account of his work and of the ideas that accompany it.

Our engineering societies are manifesting considerable interest in the Universal Exposition to take place at Paris next year, and it is likely that a large number of their members will cross the Atlantic to see the big show, and to take part in the proceedings that will be contemporaneous with it. The American Institute of Electrical Engineers has, I learn, received special invitations and tenders of hospitality from the Institution of Civil Engineers and from the Society of Arts. The latter body hopes to see the members present at its *conversazione* in June, and the Civil Engineers propose to make such arrangements as will render the visit as useful and agreeable as possible. Similar invitations have been extended to the American Society of Civil Engineers and the American Society of Mechanical Engineers, and it is understood that the three bodies, joined perhaps by one or two others of similar character, will arrange to make a combined trip, all the members and delegates going over together. The present indications are that the number of members and their families will be so great that it will be necessary to devote a steamer exclusively to their use, and negotiations with this in view are already going on with the steamship companies. This being the case, you may as well be prepared for an influx of American scientists and professional men.

Electric railways are beginning to fill a large place in the public eye, and the big cities are becoming jealous of the facilities already enjoyed by the inhabitants of smaller places that they have been inclined to look down upon as provincial and slow. Boston has just got its Sprague and Bentley-Knight road into operation, and at last the conduit for the Bentley-Knight system is being laid down in Fulton-street, between the tracks that have already been there for at least a year. Our New York aldermen also, after a spell of stupid opposition, have yielded to the inevitable, and have voted to allow the operation of the Julien storage battery cars on the Fourth Avenue-road.

Digitized by Google

The situation daily becomes more hopeful and promising, and the claims of the electric railway people do not lose any of their vigour or effect, from the fact that Mr. C. B. Holmes, who is one of the most prominent cable railway men in the country, has just invested some of his own money and that of other people in the electric railroad at Los Angeles, California, where he promises that the finest electric service in the country shall soon be in operation. Mr. Holmes is a keen, far-sighted man, who began with horse railways, then gave Chicago its present cable system, and now tenders his support to electricity as the coming thing.

VIENNA NOTES.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, *January 5 h.*

On the 19th December the Vienna Town Council visited the central electric lighting station of the Imperial Continental Gas Association in the Schenkenstrasse, led by the Burgomaster, Dr. Uhl, and followed by most of the leading officials and engineers. They were received by the general manager of the company, Mr. H. V. Lindon, Dr Tiltscher, their Vienna representative, and Mr. T. W. W. Melhuish, Assoc.M.S.C.E., the engineer-in-chief. Visiting, first, the large hall, where formerly the dynamos stood (which is now turned into a workshop), a collection of various instruments and apparatus, specially arranged for the purpose, was shown to them. From here they descended by an iron staircase, passing the coal depot, to the dynamo room. This room, as well as the boiler house, is half-underground, and stands where formerly the court-yard of the house used to be. It is a very spacious, light, and airy place, covered with glass. The dynamos stand separate from the floor, and are so well put up that no vibration is felt in the room. There are, first, three Crompton dynamos coupled together, driven by Willans engines, each producing 250 amperes and 400 volts (100,000 watts); then follow five smaller ones, producing 72,000 watts each. Opposite the dynamos are the tables on which are placed the switches, measuring instruments, &c. Next to the dynamo room, divided only by a wall, is the boiler house, containing eight Babcock and Wilcox boilers, each with 131 square metres heating surface. Next to the boiler house are placed four pumps for feeding the boilers. The water being bad, a special water station for clearing the water has been built. This contains three large apparatuses, each clearing 4½ cubic metres per hour. Above them are placed the water reservoirs, containing 260 cubic metres of water.

The company are boring for water on their premises, but though the borehole has already reached 284 metres only very little water has been found. This is the more disappointing since the premises are only 176 metres above the sea, and the Danube is nearly 260 metres above the bottom of the borehole.

After having seen all the arrangements the Burgomaster thanked the officials of the company for their kind invitation, and expressed the satisfaction of the Town Council at having been able to see so splendid an installation. Considering the opposition the company had to encounter from the Town Council when they started their central station, this must be most gratifying to them. On Thursday, the 27th ult., the Society of Austrian Civil Engineers proposed to visit the station.

The well-known health resort, Marienbad, Bohemia, is to be lit by electricity next season. Thirty-five arc lamps of 1,000 candle-power each, and 50 glow lamps of varying candle-power are to be used for the public streets. As reserve for lighting private houses, about 1,300 glow lamps and 16 arc lamps are to be provided. The Town Council intend to undertake the whole installation at their own risk. The central station is to be built near the railway station, and Messrs. Ganz and Co., of Budapest, are said to have secured the contract. Overhead wires will be used.

This summer Passion Plays are again to be acted in Brixlegg, and preparations are already being made. One of the new improvements suggested is the lighting of the theatre by electricity, thus utilising one of the most modern inventions in helping to keep alive one of the few remnants of mediævalism. It is only to be feared that the special charm of these plays will be taken away by modernising them too much.

The Electric Light in Rome.—The *Bolletino delle Finanze Ferrovie* states that the municipal authorities of Rome have appointed a committee to report upon a proposal to extend the electric light to the whole of that city. The proposal has been made by the Societa Anglo-Romana per l'illuminazione di Roma col Gas ed Altri Sistemi.

CORRESPONDENCE.

THE DISSIPATION OF FOG.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the discussion commenced in your columns concerning the electrical dissipation of fogs, I venture to state that I have been considering for some time past a series of experiments in this direction, amongst which is the utilisation of a balloon, not only for the dissipation of fogs but also for the precipitation of rain. I hope before long to have some practical suggestions to make public. At present the results of my planned experiments are to me so speculative that I will refrain from prophecy.—Yours, &c.,

ERIC STUART BRUCE, M.A., Oxon,
Fellow of the Royal Meteorological Society.

10, Observatory-avenue, Kensington, W., 8th Jan., 1889.

ELECTRICAL DISSIPATION OF FOG.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I may as well take advantage of the opportunity afforded by your further note to say that, so far as preliminary small-scale experiments on different kinds of fog are concerned, they have all been done. Besides chemical smokes of various kinds I have dispersed steam, and turpentine smoke, and coal smoke, and sulphur, and mixtures of all of them. I have made stuff like that in a sulphuric-acid chamber by burning sulphur and supplying nitric acid vapour, and steam from a boiler. All manner of nameless abominations have been tried, and all are amenable to the electrical influence.

The whole question is now one of quantity. No doubt it can be done if enough electricity is sent up at a sufficiently high potential. The quantities concerned in natural atmospheric electricity are not hopelessly beyond imitation—the potentials are, except by reason of some automatic replenishing or intensifying action in the atmosphere. But for the clearing of fog, a potential sufficient to cause easy discharge from points or flames is sufficient, and this I believe is attainable, even combined with the requisite quantity. But it is not a small matter; a good many horse-power are necessarily involved, and unforeseen difficulties may arise as soon as large scale experiments are attempted.

It is a thing that, sooner or later, however, must be tried, and there is nothing but cost to prevent the trial being soon.

Perhaps I may trouble you to reprint the following extract from the *Journal* of the Royal Institution of Great Britain (for May, 1886). It was the conclusion of my Friday evening lecture there some three years ago.—Yours, &c.,

5th January, 1889. OLIVER J. LODGE.

[EXTRACT.]

"Leaving these sublunary and industrial applications, let us ask finally if there may not perhaps be some possible mode of artificially affecting atmospheric conditions by means of electricity. It certainly seems to me rather probable, and I should much like to have the means of discharging a large quantity of high-pressure electricity into the air, either for the purpose of acting on a fog, or in the hope of perhaps affecting the weather.

This much I regard as certain, that if a kite or a captive balloon (a kite for windy days, a balloon for calm ones) be flown into a cloud, and made to give off electricity for some time, that cloud will begin to rain.

It is just possible, though hardly probable, that by the automatic coalescence of drops into larger ones, the potential of the charge so given could become high enough to cause an artificial thunderstorm.

The amount of electricity in a thunderstorm is not very great (Faraday reckoned it as less than the amount in a thimble-full of water, and he was quite right); its potential is enormous, but there is certainly some automatic regenerative action going on in the atmosphere, which is able to raise the potential of a given charge higher and higher until a flash occurs.

It is well known, from observations made with Sir W. Thomson's atmospheric recorder, that variations in the electrical condition of the air precede a change of weather; but it is not known which is cause and which is effect in this case.

With a very large voltaic battery, such as that constructed by Dr. de la Rue, or perhaps even a bigger one, of sufficient E.M.F. to give a constant brush discharge from points, a tremendous quantity

Digitized by Google

of electricity could be poured into the atmosphere, and its electrical condition could be certainly disturbed.

Whether this disturbance would be beneficial or not is, I know, another matter. I do not see how one is to tell without trying the experiment.

Perhaps usually the weather is best left alone; but there are times when any change feels as if it must be for the better.

Very little is known at present concerning the causes operating in the formation and dissipation of those cyclones which act so powerfully on our climatic conditions as to be now the main object of study with meteorologists, since Mr. Buchan proved to us their existence and showed us how to study them. Some of them are gigantic, but some are small and almost local whirls. A long way we are at present from even entertaining the idea of artificially controlling them; but we have learnt to control a great number of natural agents—torrents, cataracts, fire, electricity, and the main effect of a thunderstorm on a civilised town is now merely to clear its air and stir up its lightning conductors. Storms, earthquakes, and volcanoes, we have not yet learnt to control, perhaps we never shall. Perhaps also we may always remain unable to exert any effect, even on ordinary winds, clouds, and rain; but the interests involved at certain seasons of the year in the presence or absence of a succession of rain-compelling cyclones, or of frost-and-sun-transmitting anti-cyclones, are so prodigious, that even the barest glimpse of the possibility of exerting any kind of effect upon these great agents is worth attention, and it is a subject eminently suited for experiment. The experiments, however, must be on a large scale, and must be costly. Were it not so, I for one should not hesitate to make some preliminary attempts in the direction indicated."

ELECTRIC TRACTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am sorry to take up valuable space in your journal for the purpose of defending myself against the repeated attacks of Mr. T. Parker, who assumes now that I have produced a novel form of battery plate merely for the purpose of "getting around or evading the patents held by the Electrical Power Storage Company," and alleges having "seen similar plates either in the day of his (my) connection with this company or previously, these plates having been set aside on account of their difficulty and cost of construction." I had the privilege of being connected with the Electrical Power Storage Company at the time when the works were organised, and for a considerable period afterwards, but no attempts at making similar plates ever came under my notice. I had occupied myself with secondary batteries before this eminent company, or any similar company, existed in this country. My intention for many years had been to produce a plate which would stand rough usage and high rates of discharge with a minimum depreciation. Some time after I left the Electrical Power Storage Company I commenced experiments with the object of producing plates of the description given in *The Electrician* of Dec. 14th, 1888. The difficulties I experienced were very great, just as Mr. Parker imagined when penning his letter, and I resolved more than once to discontinue the work, which had worried my mind and involved so much time and expense. But I could no more give up the idea of improving secondary batteries than relinquish my favourite subject, electric traction. I continued, with the assistance of Messrs. Stephens and Smith, until we brought the battery to a commercial success, which success is warranted by our ability to make traction cells at a reasonable cost, and maintain them at the rate of one penny per car mile on ordinary tramways.

Although proud of my achievements, I would willingly recommend purchase or use storage batteries of anybody's make if they proved to be cheaper and more durable than mine. I am just as anxious as Mr. Parker that the "public shall be thoroughly cognizant of all its merits," and if I have been the means of raising the status of the storage-battery industry, and have at the same time proved its utility for electric traction, I am satisfied, for the reward is steadily flowing in.

I have no desire to discuss the technical details any further, they have to stand on their own merits; but in connection with the very delicate points raised by Mr. Parker I may add that some time ago, when our success was fully assured, friends of mine approached Messrs. Elwell-Parker and the Electrical Power Storage Company with a view of inducing them to utilise my invention, but neither of those firms cared to take it up, nor did they seem to appreciate its advantages.—Yours, &c.,

London, January 7th, 1889. A. RECKENZAUN.

THE RECKENZAUN STORAGE CELL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I think it only justice to Mr. Reckenzaun to state that no plate resembling those described in your issue of Dec. 14th last was made or suggested during the time I was engaged as chief electrician to the Electrical Power Storage Company. All experimental work passed through my hands from the day the works and laboratory were started until I left, early in 1884. I think Mr. Parker must be under a wrong impression. I can also state the fact that Mr. Reckenzaun worked on electric traction problems long before the Electrical Power Storage Company existed, having seen various devices at his house at that early period.—Yours, &c.,

CH. CAPITO.

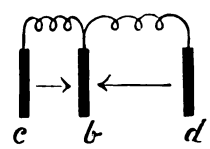
9, Belgrave-terrace, Lee, S.E., Jan. 7th, 1889.

PRIMARY BATTERIES FOR LARGE CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Ross in his letter of the 24th ult. gives certain reasons why primary batteries may be installed to greater advantage on a large scale. Undoubtedly this is so, but by far the most important of the points enumerated is that referring to the utilisation of products. If Mr. Ross can show that the products referred to, made on a large scale, will meet with a correspondingly large and remunerative demand, and that the cost of lighting by this method can be reduced to that by the engine and dynamo, there will then be a truly promising future for the primary battery.

As the success or failure of the primary battery as an extensive lighting agent lies almost entirely in the solution of this problem, I venture to offer a suggestion whereby some of the products may be utilised again for further action at the expense of a comparatively cheap acid. I refer to the principle of regeneration, which I think has hardly received the attention that its many advantages would have justified. It is not only possible to construct a cell that will revivify its own depolarising solution when at rest, but will do so when in action. If the negative plate of a primary cell consist of two such substances as copper and carbon, a secondary and local action may be established whereby, in the case where hydrochloric acid is employed, a chloride of copper will be formed. This chloride being soluble in hydrochloric acid performs the function of depolarisation. Now, it may seem somewhat illogical to assume that two opposing actions can take place at the same time; but the following diagram will, I think, show that although the



E.M.F. will be lowered by reason of the tendency of the deposited copper on the zinc side to reform into a chloride, still it is possible that such action can go on outside the influence of the main circuit. In the diagram given *a b* and *c* are respectively zinc, carbon, and copper plates, and the arrows show the direction of the currents under the liquid. As soon as the cell is set up chloride of copper is formed at the copper plate, the circuit between the copper and carbon being always closed, and this action continues whether the main circuit be closed or open. If the main circuit between the zinc and carbon plate be closed, hydrogen forms on the carbon, and is immediately taken up by the chlorine of the copper chloride, copper being deposited. When the main circuit is open the chlorine of the acid attacks the copper deposited on the carbon, much in the same manner as an unhomogeneous zinc will be rapidly deteriorated by small local closed circuits, and hence the cycle of actions is kept up at the expense of the hydrochloric acid.

Digitized by Google

By such a system it will be seen that a comparatively cheap acid is all that is necessary to replenish the negative vessel, that there is no useless remnant of a partially expended and expensive depolarising fluid, and that the internal resistance remains a constant quantity. I have carried out various experiments with this class of cell, and have obtained remarkable constancy; but as it stands I fear the internal resistance is somewhat too high for lighting purposes, although it is consideraby under that of a Leclanché of same capacity. I hope soon to be able to give some further particulars; but in the meanwhile I have brought the subject forward with a hope that others will be induced to enter into a very promising field of investigation.—Yours, &c., N. G. Thompson.

7, Westminster-chambers, Jan. 8.

[Our correspondent's ingenious idea does not, however, touch what is, after all, the real *crux* of the problem, namely, the regeneration of the zinc.—Ed. *E.*]

THE APPLICATION OF THE PROJECTOR IN THE TRAINING OF HEAVY GUNS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I notice your extract from a contemporary, referring to Messrs. Goolden and Co.'s proposal to apply electric projectors to the sights of guns, and your reference to my experiments with range-finding appliances. You will, doubtless, recall our conversation on the subject some 18 months ago, soon after my return from Chili. Since then I have met many officers who have used the projector for range-finding, with different degrees of success.

Though there is no novelty in Messrs. Goolden and Co.'s proposal, it will be interesting to see the details of their plan for mounting search lights on guns. I have tried this, and know something of the practical difficulties involved. The measure of success which attended my work in this direction was mainly obtained with an arrangement in which powerful projectors were mounted on circular platforms above the machine guns of a cruiser. Both projectors and guns were mounted on the masthead, and had thus a very wide range. The angle was read off to the gunner immediately below, and excellent practice could be made within ranges of 1,000 yards on the darkest nights. But I question the expediency of actually connecting projectors with the sights of guns. In my opinion the further the projector is removed from the gunner the better. One of the first of naval qualifications is powerful eyesight, and nothing is more trying, perhaps nothing more ruinous to the eyesight, than the manipulation of search lights. The glare of light from a ship's deck which would result from the use of so many lights would seriously interfere with the navigation of the vessel. The best method, perhaps, is that now most in use, viz., the application of the projector, not to gun sights, but to the range-finder. The development of naval electric appliances may well be left in the hands of the numerous energetic young naval electricians among the officers of our squadrons, who understand the problems they have to tackle, and appreciate the value of electricity as an ally to accuracy and rapidity.—Yours, &c.. Alfred E. Mavor.

Forth Bridge, South Queensferry, N.B.
January 8, 1889.

ELECTRICITY METERS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The use of electricity, either as a lighting or as a motive agency, necessarily implies the use of some kind of instrument to measure the power used by the consumer. So far as my experience goes I do not know any meter that unites the qualities of a simple and accurate measurer of the energy actually consumed, but as many electricians have doubtless solved the problem to their own satisfaction, I think it would be of general interest to your readers if they would publish in your columns the results of their experiments,and their opinion as to the best meter in the market.—I am, &c.,

John F. Forrest.

Glasgow, January 4, 1889.

BLONDLOT AND CURIE'S ELECTROMETER.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I was much interested by your description of MM. Blondlot and Curie's electrostatic wattmeter, as about two years ago I was working upon the same lines and devised an instrument which seems to have been not unlike theirs, and which consisted of a quadrant electrometer with a needle whose opposite halves were insulated from each other.

The method of using the instrument can be best explained with the aid of a diagram.

If A and B, 1 and 3, 2 and 4, were respectively connected together, an ordinary quadrant electrometer was the result. I proposed to use the instrument as a wattmeter by connecting together 1 and 2, 3 and 4 respectively, and joining A and B to the terminals of the conductor by which the watts to be measured were absorbed, and 1 and 4 to the terminals of a known non-inductive resistance in series with it, or else joining A and B to the non-inductive resistance, and 1 and 4 to the other conductor.

But whether the quadrants were designed according to the "pill-box" or the "cylinder" pattern a difficulty arose which seemed inseparable from the kind of instrument, and which ultimately compelled me to abandon my plan, and I am curious to know whether MM. Blondlot and Curie consider that they have surmounted it.

The difficulty is as follows:—If V_1 V_A denote the potentials of 1 and A at any moment, and a similar notation be employed for the other bodies, it is very easy to prove that, when the instrument is in adjustment, and 1 and 2, 3 and 4 connected, the moment of the forces on the needle round its axis is proportional to $(V_1 - V_4)$ $(V_A - V_B)$; but the action on the needle is, nevertheless, not in general a pure couple, as is the case in the ordinary quadrant electrometer, at least in theory. For example, if V_A, V_B, V_4, are nearly equal, but V_1 widely different from them, the needle, as a whole, will experience a force urging it towards 1 and 2, and away from 3 and 4, besides a couple tending to turn it round its axis, and the effect of this force will be to displace the axis of rotation relatively to the quadrants, and thus to throw the instrument out of adjustment; and so the above formula will no longer apply.

If V_1, V_4, and V_A are nearly equal, but V_B widely different, a similar displacement of the axis of rotation will result; in fact, owing to the unsymmetrical character of the arrangement, it is only in the case in which $V_A + V_B = V_1 + V_4$ that the action on the needle is a pure couple, and the formula given may be expected to hold.

I have mentioned specially the cases in which three of the potentials were at any moment nearly equal, while the fourth was widely different, as these are the conditions during the measurement of the power absorbed by a transformer while its secondary circuit is open. The uncertainty of such a measurement when made by a wattmeter possessing self-induction was insisted upon in *The Electrician* some time ago, though its importance from a commercial point of view seemed to me to have been somewhat exaggerated, and it is a curious coincidence that exactly the same case should for such a widely different reason prove the most unfavourable one to the electrostatic wattmeter.

These considerations are the more important because it appears to be very probable that the "coefficient of aberration" of quadrant electrometers mentioned by Prof. Ayrton is also due to slight departures from symmetry, which make the

Digitized by Google

position of the axis of rotation of the needle when the quadrants are all connected together dependent upon its potential relative to them, though of course the "aberrations" of the electrostatic wattmeter will be enormously greater.—Yours, &c.,

L. R. WILBERFORCE.

Spring-grove, Isleworth, January 9, 1889.

[We may remark that in the Blondlot and Curie instrument the objection raised by our correspondent is, *to some extent*, obviated by the suspension of the needle from the top and bottom of the case, as in a marine galvanometer. But it is, perhaps, questionable whether the remedy is perfect.—ED. *E.*]

THE ELECTRIC LIGHT AT GALWAY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It may interest you to know that out here in the far west of Ireland electric lighting is making its way. For some time we have illuminated a part of the old town with arc lights, and we are busy now with incandescent lighting for private work, and we have a number of engines for motive power. We are a private local company, represented professionally by Mr. James Perry, M.E., the county surveyor of Galway, and Mr. Arthur W. Slater, A.I.E.E.

We have acquired some extensive mills, with ample water-power, and have made arrangements for more power should we at any time require it.

Our proposals for lighting towns are being considered, and it looks a good sign that the commissioners have informed the gas company that their arrangement with them may end with the financial year.

As soon as our mains are completed we shall be in a position to supply our numerous customers. Our lighting has had the effect of reducing the price of gas from 6s. 6d. to 4s. 9d. per 1,000 cubic feet.

Trusting this information may interest you.—Yours, &c.,

THE GALWAY ELECTRIC COMPANY.

THE INVASION OF BATH BY THE HOUSE-TO-HOUSE COMPANY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As many of your readers are aware, I have just succeeded (after three years of unremitting efforts) in inducing my fellow-citizens to introduce the electric light into Bath for public and private use, and have obtained from the Corporation a seven years' contract (on behalf of a local supply company) for the public lighting of fifty of the principal streets, squares, and crescents of this city with arc lamps. Plant will shortly be put down for 200 arc lamps and 1,000 incandescents.

I am not, as many suppose, a professional electrical engineer, but only an enthusiastic admirer of "the light of the future." During the past four years I have unstintingly spent my own time and capital in introducing electricity into several towns in the West of England, in the prosperity of which I am personally interested.

To my surprise, just as we are on the eve of forming our local company, the House-to-House make an application to the Bath City Council asking them to sanction their applying to the Board of Trade for a license for lighting the same area for the same term of years. What is the meaning of this application? Are the House-to-House Company imitating the behaviour of the Maxim-Weston Company under the chairmanship of Mr. Hugh Watt, M.P.? The unjustifiable interference of the Maxim-Weston some twelve months ago, just as the Commissioners of Sewers were contemplating entering into a contract with the Brush Corporation for the lighting of the City, was not only a loss to that particular company, but still more so to the whole of the electric lighting industry. The only effect of this application is to frighten a certain number of timid investors, who will be afraid to apply for shares in the Bath Electric Lighting Company if labouring under the mistaken impression that it is going to be subjected to the competition of a powerful London company with an unlimited amount of capital behind it.

Even if the House-to-House possessed the necessary capital to erect a large central station they would obtain no custom, as they could not compete with the local company except at a ruinous loss. The sooner companies which pursue this "dog-in-the-manger" policy cease to exist the better it will be for the electric lighting industry, the growth of which they retard by their short-sighted policy.

Trusting that this candid expression of my views may produce beneficial results.—Yours, &c.,

H. G. MASSINGHAM.

ALLEGED PIRACY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We have noted in your last issue a letter signed S. Sudworth which evidently refers to our firm and catalogue, and in answer thereto we can only state that the assertions made therein have no foundation in fact. At the same time we wish to mention that Mr. E. L. Berry, whose name was referred to by Mr. Sudworth, has written to us saying that the letter was published without his knowledge or authority.—Yours, &c., G. BINSWANGER AND CO.

5, Great St. Thomas Apostle, 7th January, 1889.

EXECUTION BY ELECTRICITY.

BY SYDNEY F. WALKER.

The State of New York has decreed that from henceforth, if men must die by the hand of the law, electricity shall be the agent employed and not the rope.

The object of the law is, apparently, to secure that death shall be more painless, and that there shall be no chance of the painful scenes that have been so common at the gallows within recent years.

While fully recognising the humane spirit which has prompted the enactment of this law, is it really humane after all? Is it clear that death by electricity, in the present state of our knowledge of the subject, will be more painless and more sure? Do we know how to kill a man surely and painlessly? The writer ventures to affirm that no one can furnish rules for killing a cat surely by electricity, and without pain, much less a human being in the full vigour of man or womanhood.

It is assumed by the humanitarians who have procured the passage of the law, and apparently by the criminals whom the *Sun* reporter interviewed upon the subject, that all that would be necessary would be for the condemned man or woman to seat himself or herself in an armchair, and sleep off. And the ground for this belief is the number of deaths that have unfortunately occurred through incautiously handling wires and apparatus carrying high-tension currents. As a matter of fact, we are at present in absolute ignorance of how these people have been killed. We have nothing to guide us as to the electromotive force or current to be employed, nor whether these should vary with the age, size, weight, or sex of the object. The accounts furnished are most contradictory. In the early days of electric lighting, several deaths occurred from incautiously handling the wires and lamps carrying alternating currents. In one case, that of the stoker on board the Czar's yacht "Livadia," the voltage could not have been high, if the reports were correct. More recently, responsible American electrical engineers have stated that the alternating current is not so likely to be fatal as the continuous current, and instances have been mentioned of 1,000 volts being taken through the hands without injury. Again, there was the case at the Health Exhibition, where a man was killed by 1,200 volts from a continuous-current machine; and more recently a waitress at the Newcastle Exhibition received a very severe shock from incautiously touching an arc lamp on a circuit, the full tension of which was only 200 volts. The writer has himself repeatedly received the shock of 200 and 300 volts, plus the extra current generated on breaking the circuit of a series machine. M. d'Arsonval has stated that he has killed guinea pigs with 60 volts.

But if all the reports and all the experience available be put together, the knowledge imparted as to how the current acts inside the body, or what it does, is not equal to that possessed by a first year's student of electrical engineering, respecting the action of the electric current upon every apparatus that he handles.

Even the use of electricity for healing purposes is mere guess work. No member of the medical profession has followed the current inside the human body, in the same way that the electrical engineer follows it into electrical apparatus. Even the most

Digitized by Google

advanced of electro-medical scientists has only discovered that there are enormous differences in the electrical resistance offered by the human body, as great as from 500 ohms to 6,000 ohms; and even he cannot tell us how the current divides when it is inside the body, nor what is its effect upon each membrane, bloodvessel, &c. And if this is so, will not the earlier executions, at any rate, resolve themselves into experiments? and further, will not a great number of experiments be necessary before a simple rule can be formulated, such as should be available for the old method. Is not the idea of a healthy man, clad in woollens or cottons, seating himself in a wooden arm-chair, however much patented, and sleeping off, sheer nonsense? How is the current to be applied? Is it to pass through the wood and the clothes of the criminal, and if so, what tension will be required, and how will the operator be insulated himself?

Prof. E. J. Houston has pointed out in an able Paper recently read before the American Philosophical Society, that for death to ensue, some vital part of the body must lie in the path of the current, such as the brain, the lungs or the heart; and that in those cases where death has been caused by electricity, the current has passed either from the head or neck to the feet, from either arm to one or both feet, or, lastly, from hand to hand. Would not some arrangement have to be made involving similar conditions where the object was to kill? and would it not necessitate pinioning, the procession, and all that condemned criminals so justly dread? Further, are there not far more chances of an electrical apparatus going wrong, especially in the only hands that could be got to work it, than the rope? Is not the problem of killing a man by electricity, under the necessary conditions, a hundred times more difficult than the simple mechanical problem involved in hanging?

If, then, blunders occur on the old plan through sheer carelessness where it is difficult to fail, would they not be almost certain under conditions requiring great skill and care? Would it not be wiser, therefore, to adopt the old-fashioned plan of learning how to do a thing before experimenting on human beings?

Will any humanitarian imagine to himself a criminal tied in his chair, tied to his conductors, the funeral service going on, and the operator vainly endeavouring to get the apparatus to work, perhaps owing to a change in the weather, each moment growing more and more nervous; and ask himself if that would not be a step back to the old days of torture?

Let humanitarians and members of the medical profession first study the human body as an electrical apparatus, and a very delicate one; let them follow the current in each of its numerous paths inside the body, and ascertain what its effect is on each organ, each membrane, each nerve, &c., and then, if they think well, let them arrange to execute by electricity, as they should then be able to accomplish it surely and painlessly; and more than that, the knowledge so acquired should be of more value to them and to the human race than all the books on medicine that were ever written.

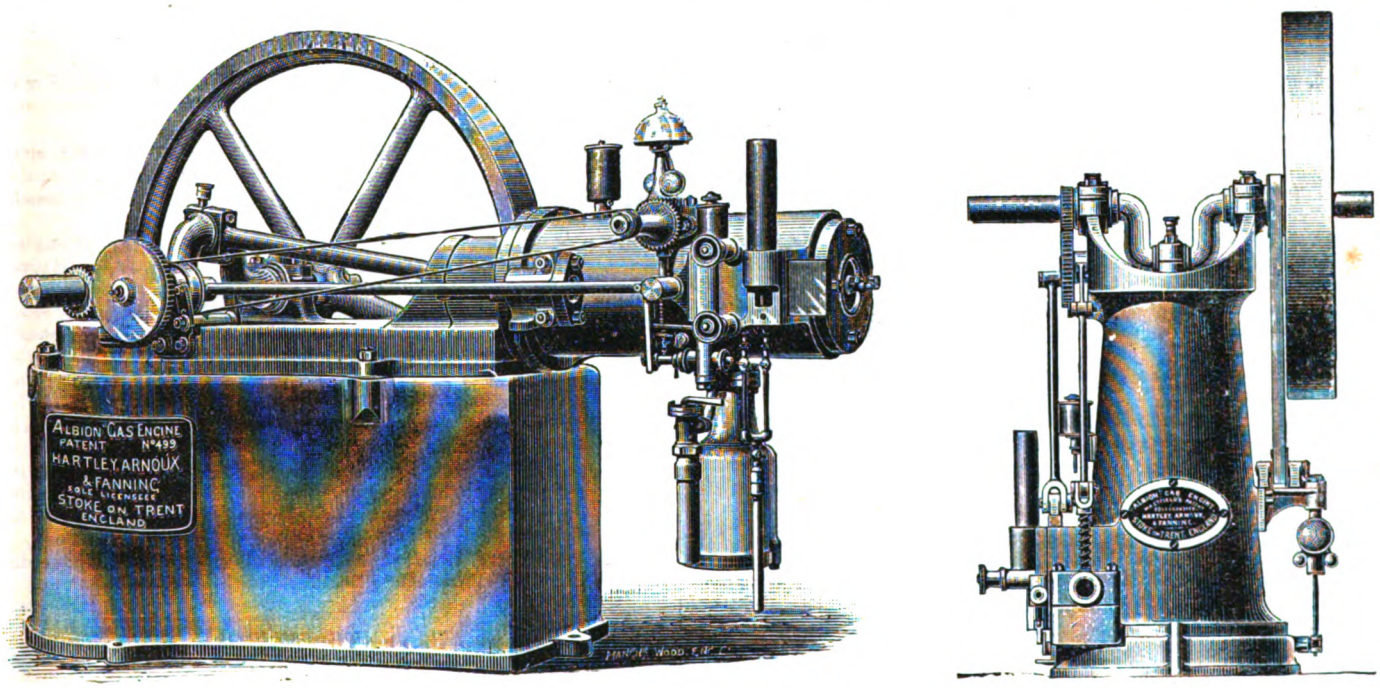
THE "ALBION" GAS ENGINE.

This gas engine, which has recently been introduced by the Albion Engine Company, is of a new type, and will, it is said, run with a consumption as low as 13½ cubic feet of gas per nominal horse-power per hour, including the firing jets. We know of no other gas engine which is capable of equalling this performance, and if verified it would mark a very decided improvement. The engine is made either horizontal or vertical, as shown in the adjoining figures.

In the construction of the engine the great aim has been simplicity, with the result that it contains a very small number of parts. The slide works on the side of the engine, the charge is fired from the centre, and the combustion of the gas being practically perfect, we are told that no carbon is deposited in the passage of the slide over the ports, and the slides will, as a consequence, run for months without removal. The engine can be run at a slow speed, or accelerated to 350 revolutions per minute.

With some gas engines in the market the cost of oil, or other lubricant, is very high. This, it is claimed, is not the case with the Albion gas engine—firstly, because of the much fewer parts, and, secondly, owing to the easy and steady working of the slides. The makers guarantee to "repair or replace any parts of these engines which may be broken, or suffer from undue wear within six months after delivery."

By a special arrangement with the manufacturers of a well-known and approved dynamo, the Albion engine is now supplied for electric light installation in a very neat form. In the case of the vertical motor a special bedplate carries the dynamo, which is driven direct off the flywheel of the engine. In order to readily start it an arrangement is used allowing the motor to be started without actuating the dynamo, thus rendering starting easy, as well as enabling the motor to be utilised for driving purposes, independent of the dynamo. But at will the latter can readily be connected with the engine. The same arrangement also allows of a simple means of taking up the slack of the driving belt by means of the same hand wheel and screw which is used to couple the gas engine and dynamo. In the case of the larger horizontal engines the dynamo is bolted to the underframe of the engine, so that where space is valuable no additional room other than that on which the engine stands is needed. This forms a very neat and efficient combination, and is giving universal satisfaction to users. Full particulars of either the above engines will be forwarded by Messrs. Hartley, Arnoux and Fanning, Stoke-on-Trent.



The "Albion" Gas Engine—Horizontal and Vertical.

COMPANIES' MEETINGS & REPORTS.

Metropolitan Electric Supply Company (Limited).

An extraordinary general meeting of the members of this Company was held at Winchester House, Old Broad-street, on Tuesday, for the purpose of considering and, if thought fit, passing resolutions altering the Articles of Association of the Company as follows:—

Article 26. By striking out the words "A director may act before acquiring his qualification."

Article 45. By adding at the end of this Article the words "Provided that the power of borrowing and raising money and of making and issuing mortgages or debentures, or debenture stock, obligations, or other securities, shall not at any time, without the sanction of a general meeting, be exercised to such an extent that the total amount of principal money borrowed, raised, or secured shall exceed the nominal amount of the share capital for the time being, but this restriction shall not oblige any person taking any mortgage or debenture, or debenture stock, obligation, or other security of the Company, to inquire whether there has been any such excess, or affect the validity of any such security in the hands of a *bonâ fide* holder, nor interfere with the power of the directors to make and enforce calls."

Article 102. By striking out the words, "A Director shall not be appointed Auditor," and inserting in lieu thereof the words "No Director or other officer of the Company shall be appointed Auditor."

Article 119. By inserting after the word "shares" the words "not fully paid."

Article 121. By inserting after the word "writing" the words "which may be in the usual common form."

Article 123. By inserting after the word "Share" the words "not fully paid up."

Article 130. By striking out all the words except the words "Every shareholder shall be entitled to one certificate for his shares gratis, but in every other case one shilling shall where the Board think fit be paid to the Company for every certificate."

Article 155. By inserting after the word "Shares" in line 2 the words "not fully paid up."

The chair was taken by Alderman Sir R. N. Fowler, Bart., M.P., in the unavoidable absence of the Chairman of the Company, Sir John Pender, K.C.M.G.

The SECRETARY (Mr. E. Cunliffe Owen) having read the advertisement convening the meeting, as above,

The CHAIRMAN said: Gentlemen, these are alterations required by the committee of the Stock Exchange for the purpose of our getting a settlement. I will ask the Solicitor to explain the purport of the alterations.

Mr. CHARLES BURT stated, with regard to the alteration in Clause 26, that as a matter of law it had been decided by the Courts that a Director might act before acquiring his qualification, that he might have reasonable time to acquire his qualificaion; but the point had no application whatever so far as their Company was concerned, the Directors having long since acquired their qualification. The change in Article 45 was a limitation of the borrowing powers of the Company in the manner explained in the notice. This was a new requirement of the Committee of the Stock Exchange, and probably the shareholders would regard the requirement as a reasonable one. With reference to the alteration in Clause 102, which was also a modern requirement of the committee, there had been no intention, of course, so far as their Company was concerned, of appointing any Director or officer of the Company as auditor. Then the Committee, as regarded Article 119—which he read—desired that the lien on the Company's shares should be restricted to those shares which were not fully paid up, the object, he supposed, being to allow the shareholder to lodge his certificate with his banker or anyone else in such a way that he might raise money. As to the alteration in Article 121, it was well, perhaps, to express it, but there had been no idea of making it other than it would stand by the proposed change. In regard to Clause 123, the Committee desired them to insert after the word "share" the words "not fully paid up," so that when shares were fully paid up a transfer of them might be made to any person the transferror pleased. With respect to shares not fully paid up, it was necessary that the Board should have a discretion as to adopting those who might be proposed as transferees; otherwise it might happen, if the Company, or any company, were in difficulties, and a sum were unpaid on certain shares, the holder might transfer them to a man of straw in order to escape his liability. The object of the proposed alteration was to avoid that. The change in Article 130 was, to his mind, not of the slightest importance. The alteration in Clause 155 again applied to the question of the lien on shares, and again they were asked to insert the words "not fully paid-up." Those were the only alterations, and, if the shareholders had no objection, it would be convenient to take them all as one resolution.

On the motion of the CHAIRMAN, seconded by Sir JAMES ANDERSON, a resolution was unanimously passed agreeing to the various alterations in question.

The CHAIRMAN stated that what had been done would require to be confirmed at another meeting, but it would be merely formal.

Mr. BALFOUR then proposed, and Mr. KENNETH ANDERSON seconded, a vote of thanks to the Chairman.

The CHAIRMAN having acknowledged the compliment, the proceedings terminated.

Maxim-Weston Electric Company (Limited).

An extraordinary general meeting of this Company was held at the Cannon-street Hotel last Monday, when the subjoined resolutions, which were passed at the extraordinary general meeting of the Company held on the 21st ult., were submitted for confirmation as special resolutions:—

"1. *That the liquidators of the Company be and they are hereby authorised to consent to the registration of a new company to be named the Maxim-Weston Electric Company (Limited), with a Memorandum and Articles of Association which have already been prepared with the privity and approval of the Directors of this Company.*

"2. *That the draft agreement submitted to this meeting, and expressed to be made between this Company and its liquidators of the one part, and the Maxim-Weston Electric Company (Limited) of the other part, be and the same is hereby approved, and that the said liquidators be and they are hereby authorised, pursuant to Section 161 of the Companies Act, 1862, to enter into an agreement with such new company (when incorporated) in the terms of the said draft, and to carry the same into effect with such, if any, modifications as they think expedient.*"

The chair was occupied by Mr. John Marks.

The SECRETARY (Mr. Samuel J. Boyce) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, in moving the confirmation of the resolutions just read by the Secretary, I would draw your attention to one clause in the agreement, every word in which was read at the last meeting to the shareholders, and of the contents of which I presume they have notice. One clause, however, provides that the new Company have the power to terminate this agreement if shareholders holding 30,000 shares dissent from the reconstruction scheme. Well, we know that great efforts are being made in a certain quarter to induce shareholders to dissent from the scheme, those efforts being made merely from interested motives. Mr. Abrahams told us at the last meeting that he represented shareholders holding 30,000 shares, and that he would certainly dissent from the scheme. Well, if shareholders holding 30,000 shares only dissent from the scheme, I do not think that that would be a bar to the new company carrying out this agreement with the liquidators; but if a very large number of shareholders dissent I think that the new company would then be justified in not carrying out the reconstruction scheme, because to satisfy those shareholders the money of the gentlemen taking up the new shares would have to be applied, and that would be unfair to the latter. But I merely make these remarks to point out to you how contrary it is to your own interests to dissent from the scheme. It is all very well for Mr. Abrahams to tell us that the arbitrators will give 2s. a share to each dissentient shareholder, and that is held out merely for the purpose of inducing you to dissent; but we have a very different opinion as to what the arbitrator would give. Suppose, however, a very large number of shareholders dissent and the Company do not go on with the scheme, what will then be the position of the dissentient shareholders, and also of those who do not dissent? It will be this—that the new company would drop the scheme, and then the matter would fall into the hands of the liquidators. They will then proceed with the liquidation pure and simple, and what will the shareholders then get? If they get 3d. or 4d. per share I think they would be lucky. Do not be deluded into the belief that you will get 2s. a share by dissenting from the scheme—an idea which is merely put before your eyes to damage the affair altogether. I regret that Mr. Abrahams is not here, because I had intended telling him, as the representative of Mr. Watt, that even if the scheme does not go through (I cannot believe, though, that the shareholders will be so blind to their own interests as not to carry the

Digitized by Google

scheme)—if the Company falls into the hands of the liquidators to be dealt with finally—the matters between the Company and Mr. Watt will be carried through just the same as if the scheme is successful and the business goes on. He concluded by moving the resolutions as above, and added: Gentlemen, the agreement is here, and open to the inspection of any shareholder who wishes to see it. With your permission, however, we will take it as read, as it is a long document, and was fully read to the shareholders at the last meeting.

Mr. LOUIS SWABY, in seconding the motion, said: I think I ought to say a few words. Several shareholders have begged us, if the scheme put before you fails, to endeavour in other ways to carry on the Company. They are poor shareholders, and they have asked us to do all we can for them. The Directors have worked hard in support of your interests, and your interests alone, and I ask every honest man to back us up.

Mr. J. M. KLENCK: May I point out that this is our final scheme to you, and if you do not accept it the result will be that we shall go into liquidation, and you know the result of selling off our machinery, patents, and everything we possess, and what a small distribution that will give you. I think, however, that our Chairman has taken a rather gloomy view of the situation. A threat is one thing, but a fact is another. We hold these proxies from shareholders who are unable to attend, but who have sent them in our support, and we have not a proxy in the office dissenting from the scheme. I think the shareholders should know that, and that they should not follow those who are advising them, for their own reasons, to oppose the scheme, which is against the interests of the Company. I hope the shareholders will come into the scheme, and that in a short time we shall put the Company on a sound commercial basis—a position which it has not occupied for a long time in the past. We hope, however, that with your support we shall be able to put the Company on this commercial basis, so that we may take orders and execute them at a profit to the shareholders.

The CHAIRMAN then put the motion in the usual way, and announced that it was carried with three dissentients—Mr. Pankhurst, Mr. Robins, and Mr. Pates. He added: That, gentlemen, terminates the business we are met to transact. The forms of application for shares will be sent in due course to each subscriber; and, as Mr. Klenck says, I hope we shall find the shareholders support us in making application for the shares in the same way as they have sent in their proxies in support of the scheme.

A SHAREHOLDER suggested that with the application forms a report of the meeting should also be sent. Probably certain shareholders were dissenting to the reconstruction scheme in the belief that by not approving of it they would get 2s. a share, but if they understood what the only alternative was, as had now been placed before the shareholders by the Chairman, they might alter their present views.

The CHAIRMAN: I think it a very good suggestion that we should send the shareholders a *résumé* of what has taken place here to-day.

Mr. KLENCK: Now that the Chairman has left the chair, and before you disperse, I think it should be known to you that two of the three gentlemen who just now dissented from the resolutions are in the office of Mr. Watt; therefore, you know what their opposition comes from. I think it only right to communicate this to you unofficially, so that you may know what the opposition is worth. He afterwards added: I may mention that the three dissentients hold among them 50 shares.

The proceedings then terminated.

The Pilsen-Joel and General Electric Light Company (Limited).

An extraordinary general meeting of the above-named Company was held on the 4th inst., at the Cannon-street Hotel, under the presidency of Sir R. W. Rawson, K.C.M.G., C.B.

The SECRETARY (Mr. W. H. Trentham) having read the advertisement convening the meeting,

The CHAIRMAN said that the first business was to consider the resolution of which notice had been given, as follows:

"*That £100 each, free of income-tax, be paid to Messrs. Horace William Scriven and George Levinge Whately, in respect of their services as Directors of the above-named Company, from the 11th day of December, 1886, to the 13th day of March, 1888.*"

Most of the shareholders would remember the circumstances under which those gentlemen—it having been shown to them that by an oversight they had ceased to be qualified as directors—at once refunded the money they had received as members of the Board. As, however, he (the Chairman) stated in the circular which he had occasion to issue immediately afterwards, they were neither legally nor morally bound to have acted in such a generous manner, and he at the same time expressed a hope that the money would be refunded in due time. A shareholder had now come forward at the last stage of the Company's existence, being the opportune moment, to propose that the sum in question should be refunded. He (the Chairman) would be quite prepared to move the resolution himself, taking whatever obligation might be imposed on him for so doing, but as Mr. Gwynne, who was the largest shareholder in the Company, had come forward to propose it, he would leave it to that gentleman to move it, and he himself would be very happy to second it.

Mr. GWYNNE said that he had great pleasure in proposing the resolution, and as the largest shareholder in the Company the principal portion of the amount in question would come out of his share of the assets of the Company which might be distributed among the shareholders. When he made an offer to purchase the assets of the Company, he stated that it was his intention, as his first act, to refund the sum mentioned.

The CHAIRMAN seconded the motion, observing that Mr. Scriven and Mr. Whately were perfectly unconscious that they were unqualified by their holdings until the matter was pointed out to them at the time of the refunding of the sum in question. Nevertheless, they had done the work which they had to do as members of the Board.

Mr. J. A. FYFE objected to the money being repaid, on the ground that the gentlemen in question were not Directors at the time, and therefore ought not to receive Directors' fees; and, in the second place, he maintained that they did not deserve to be paid for what he termed their mismanagement. In his opinion they were not entitled to the money either legally or morally. He therefore strongly objected to the repayment, and added that the charges in his report (which he desired to read to the meeting) had not been answered. A large amount of stock was, he said, missing, owing to the culpable negligence of the Directors and the bad management of the managers.

Mr. GWYNNE protested that Mr. Fyfe was not speaking to the motion before the meeting, and he asserted that Mr. Fyfe had made statements which he knew to be untrue.

Mr. FYFE denied the assertion.

The CHAIRMAN said he should object to Mr. Fyfe reading his report, which had nothing to do with the motion before the meeting.

Mr. FYFE: You claim that certain money should be paid which I show by this report ought not to be paid, and is not due.

A SHAREHOLDER observed that that was the last opportunity which the shareholders would have, as a company, of ventilating their grievances, and everything ought to be allowed to be said that had to be said.

The CHAIRMAN: I wish to point out that these two gentlemen have been twice re-elected since.

Mr. FYFE: And have done exactly the opposite of what they were elected to do. Can the Secretary tell us about the stock sheets of 1884? Can they be found?

A SHAREHOLDER: That is not before the meeting.

Mr. FYFE contended that all these matters were before the meeting, and again inquired if the stock sheets could be produced.

Mr. STOBART protested against the repayment of the money referred to, that, he observed, being the only way they had of protesting against

Digitized by Google

the mismanagement of the Company. £50,000 to £60,000, he said, had been wasted by the Directors, and the shareholders were now asked to pay a sum of money for neglecting their interests. The two gentlemen to whom it was now proposed to pay money had so much interest in the Company that they did not know whether they were Directors or not.

The CHAIRMAN: What Mr. Stobart has said is so far argument, if correct, but the fact is that this money was spent before Mr. Whately came on the Board; and, secondly, it was spent before the date for which it is proposed to pay these gentlemen this £100 each, and while the Company was under the management of Mr. Fyfe.

Mr. FYFE: I deny that.

The CHAIRMAN: £35,000 was spent while Mr. Fyfe was manager.

Mr. FYFE replied that he had left his stocks valuable, and the Directors, by their mismanagement, had allowed them to be stolen. They had been stolen and pawned, he added.

The CHAIRMAN: I deny that they were stolen or pawned. The goods were sold to the best advantage we could obtain.

Mr. A. HUTTON said he objected to the proposal on legal grounds. The notice stated that the money was to be paid to Mr. Scriven and Mr. Whately for their services as Directors, whereas they were not Directors at all at the time.

The SOLICITOR (Mr. Parker) stated that they were not qualified as Directors, but they did their duty as Directors, and it was for their services as Directors that the money was proposed to be paid to them.

The CHAIRMAN: And they were re-elected by the shareholders when they were in the same position.

Mr. GWYNNE: These gentlemen were not qualified for this reason: that owing to some alterations made at a previous meeting the nominal value of the shares had been reduced.

A SHAREHOLDER: They held double their qualification originally.

After some further observations from Mr. FYFE, who stated that the "game" from the beginning had been to dispose of the Company's property,

The CHAIRMAN put the motion, and stated that five had voted for it and six against it.

Mr. GWYNNE then demanded a poll, which was at once taken, at the close of which

The CHAIRMAN said the scrutineer (Mr. Gwynne) reports that the number of votes in favour of the resolution is 8,102, and the number opposed to it is 1,010. The resolution is therefore carried. We now proceed to the two resolutions which were agreed to by the requisite majority at the last meeting, and which now require confirmation. The first is:

"*That the Company be wound up voluntarily under the provisions of the Companies Acts 1862 to 1886.*"

Mr. WHATELY seconded the motion.

Mr. HUTTON proposed an amendment, adding to the resolution the words "under the supervision of the Court."

Mr. BROCKLEHURST seconded the amendment.

The CHAIRMAN stated that the proposal should have been brought forward at the last meeting; at the present meeting the resolution could only be accepted or rejected. He put the motion in the usual manner, and declared it carried by nine to four. Continuing, he proposed the next resolution, as follows:—

"*That George Shead, of No. 9, Laurence Pountney-hill, Cannon-street, in the City of London, chartered accountant, and William Henry Trentham, of No. 4, Stanhope-street, Euston-road, engineer, be and are hereby appointed joint liquidators for the purposes of such winding up.*"

Mr. WHATELY seconded the motion.

The CHAIRMAN put the motion, and declared it carried by seven to four. In announcing the close of the business of the meeting he stated that he had been on the direction from the beginning. He had worked hard, though he desired to say nothing about that; but he wished to express his sense of the courtesy and kindness he had received from the shareholders, and his regard for his colleagues. He wished also to express to his fellow shareholders—fellow sufferers with himself—his regret that, not through the fault of the Directors, but by the course taken with regard to them, they had been landed in a position not very different from most of the electric lighting companies, and with a less loss than most of them.

The proceedings then terminated.

NEW COMPANIES REGISTERED.

ELECTRO-GALVANIC MACHINE COMPANY (LIMITED).—This company was registered on the 1st inst. with a capital of £3,500 in £1 shares, to acquire the letters patent granted to John Douglas and Henry Abbott, for improvements in machinery or apparatus for producing and administering electric shocks and currents, and for exhibiting advertisements, dated 1st October, 1887, No. 13,326. Registered without special articles.

E. PAGE AND COMPANY (LIMITED).—This company was registered on the 28th ult., with a capital of £30,000, divided into 30,000 shares of £1 each, to carry on the businesses of an agricultural, mechanical, marine, and electrical engineer, and of an iron and brass founder and ironmonger in all its branches. To acquire the business now carried on by James Woodward Hill, trading as E. Page and Company, at Bedford, in the County of Bedford. There is not to be less than four nor more than six directors; qualification, 50 shares; the first directors are to be paid the sum of £50 per annum each, with an additional £50 for the chairman.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended January 4th, 1889, amounted to £3,755.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during December was 4,323, estimated to produce £3,500, against 3,925 messages, producing £3,373 in the corresponding month of last year. The traffic receipts for September, estimated at £2,700, realised £2,774.

DIRECT SPANISH TELEGRAPH COMPANY.—The traffic receipts of this company for the month of December were £1,908, against £2,004 in December, 1887, showing a decrease of £96.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of December, 1888, amounted to £59,831, against £57,703 in the corresponding period last year.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of December, 1888, amounted to £38,699, against £38,908 in the corresponding period last year.

EDISON-SWAN UNITED ELECTRIC LIGHT COMPANY.—In consequence of the alteration in the numbering of Victoria-street, Westminster, the address of this company will in future be 100, Victoria-street, London, S.W., instead of 13, Albert-mansions.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts for December, 1888, amounted to £22,000, and for the period from 1st January to 31st December, 1888, to £272,000. For the corresponding months of 1886 and 1887 they amounted to £258,600 and £264,480 respectively.

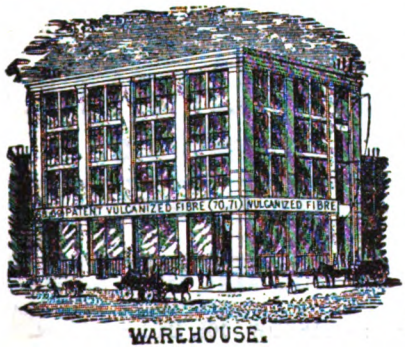
METROPOLITAN ELECTRIC SUPPLY COMPANY.—Application has been made to the Stock Exchange Committee to appoint a settling day in, and to grant a quotation to, the shares of the Metropolitan Electric Supply Company (Limited).

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The traffic receipts of this company for the month ended 31st December, 1888, amounted to £4,475.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended January 4th, 1889 (after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company), were £3,228.

NOTICE OF REMOVAL.—The offices of the Cuba Submarine Telegraph Company (Limited) have been removed to No. 58, Old Broad-street, London, E.C.

THE NON-CONDUCTOR OF ELECTRICITY.



WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

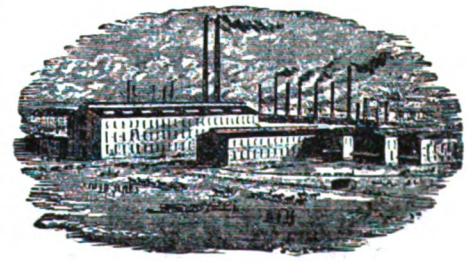
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

ENDLESS TELEGRAPH PAPERS.

(As supplied by Waterlow and Sons, Limited, to Her Majesty's Postal Telegraphs.)

These Papers are kept in stock in large quantities, and can be cut to any width for the **MORSE, WHEATSTONE, HUGHES,** and other machines; also the **RECORDER** Printing Paper, as used on the various Electric Automatic Printing Instruments.

COLLOTYPE PRINTING.

High-class Reproductions in Facsimile of Monochrome Drawings, &c., specially useful for the Illustration of Trade Catalogues.

PHOTO-INTAGLIO ENGRAVING ON COPPER; PHOTO-ZINC ETCHED BLOCKS.

Photo-Lithography and Photo-Engraving and Printing in all its branches.

WATERLOW & SONS, LIMITED,

27, GREAT WINCHESTER STREET, LONDON, E.C.

VULCANITE

SHEETS, RODS, TUBES, CELLS, &c., for Electrical Purposes,
MANUFACTURED BY
THE NORTH BRITISH RUBBER CO., LIMITED.
EDINBURGH; LONDON, 57, Moorgate-st.; MANCHESTER, 6, Charlotte-st., LIVERPOOL, Cereal-court; GLASGOW, 106, Buchanan-street.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 557.—Vol. XXII. FRIDAY, JANUARY 18, 1889. Price 4d.

NOTES.

The audience which assembled on Thursday evening last to hear Sir William Thomson's Address was probably the largest and was certainly one of the most enthusiastic and distinguished gatherings which the Society (or Institution) has ever witnessed. In the opening passages of the address, after paying a tribute to the memory of his predecessors, Sir William Siemens, Mr. Frank Scudamore, Mr. Walker, Colonel Champion, and Sir Charles Bright, who have passed away, the President referred in graceful terms to the addresses of Mr. Preece (1880), Mr. Willoughby Smith (1883), and Prof. Hughes (1886), who had each given expression to the keen desire for a mechanical explanation of electrical phenomena. To a masterly exposition of the results so far achieved in this direction the chief part of the Address was devoted. But before embarking upon this great—in other hands we might even say, perilous—undertaking, Sir William touched lightly upon several topics of lesser difficulty. Speaking first of the application of theory to signalling in submarine cables, he referred to his early researches, which proved that electro-magnetic induction did not need to be taken into consideration. But quite recently, within the last few weeks, Sir William has carried out an even more complete investigation of the problem, and has arrived at the result, also independently discovered by Mr. Oliver Heaviside, that in cable signalling "electro-magnetic induction is a positive benefit." Sir William dwelt for some time in terms of admiration on Mr. Heaviside's work, especially in connection with the telephone problem, which Mr. Heaviside has gone into very deeply. This led up to a brief consideration of the general problem of the distribution of periodic currents in conductors, with special reference to the conditions which prevail in the case of the currents used in the commercial distribution of electricity by means of transformers. In this connection information of great practical importance was imparted. Arriving now at the great questions of electro-magnetic theory and the relations of "Ether, Electricity, and Ponderable Matter," the President first expounded the analogy between the equations of motion of a viscous fluid—first given by Prof. Stokes—and the induction of electric currents, pointing out the failure which occurs in the endeavour to include a physical analogue of the electrostatic effect. From this he passed on to the "elastic solid" line of thought, reading a most interesting extract from a Paper which he had contributed to the *Cambridge and Dublin Mathematical Journal* forty-two years before. The problem therein considered has occupied his well-nigh unremitting attention ever since. Here he recorded his conviction in the words, "Whatever the current of electricity may be, I believe *this* is a reality, *it does pull the ether round.* I do not think this is a dream of electro-magnetic theory—I believe it to be a reality." He proceeded to show that if the effect consists merely in the rotation of the ether through a certain angle (corresponding to the current strength), so that a constant torque produces a constant angular displacement, and does not produce continued rotation, this could only be explained on the supposition that the molecules of matter possess inherent rotations of their own. This part of the subject was illustrated by some beautiful experiments with the gyrostat, and its curious behaviour was watched with the utmost interest. Sir William then explained and exhibited a model of his remarkable conception of the "molecular skeleton" framework of constant area. If a gyrostat could be placed in each cell, this would represent a medium possessing many of the most singular properties exhibited by the ether. Some further experiments with the gyrostat brought this memorable Address to a close.

If the electric dissipation of fog should prove to be practicable under open-air conditions, we shall next have to consider how far its realisation is a commercial possibility. And although this is, perhaps, running ahead a little faster than we have any actual warrant for, yet no harm can be done by hazarding the opinion that from this point of view the most promising—if not the *only* promising—method, would be the employment of high potential alternate-current transformers. A compound transformer, or battery of transformers, to give fifty or a hundred thousand volts, fixed on the top of the lamp-posts, and supplied with an alternating current from the regular service main, comes as near as anything we can at present see towards the realisation of Dr. Lodge's idea, although it must be admitted that high-potential transformers are likely to be somewhat expensive luxuries. The fog on December 31st, however, cost the Metropolis nearly £10,000 for gas alone—to say nothing of railway and street accidents, loss of time, loss of health, and general miseries—so that there really ought to be no difficulty in finding the money required for an experiment which is, to say the very least, not unpromising. In the case of fog, prevention is most emphatically better than cure, and if we can get rid of fog at the expense of a shower of rain, and at the same time reduce our gas bills, no effort should be spared to attain a consummation devoutly to be wished.

MUCH as we may regret the withdrawal of the electric light from the streets of Leamington—a step on which the Town Council have finally resolved—yet we have from the first consistently deprecated the introduction of any system of low candle-power for street lighting. Holborn Viaduct, Pentonville-hill, Leamington—not to add Barnet—ought surely to teach the lesson that the public will inevitably denounce as a failure any electric light unless it outshines the gas to which they were previously accustomed. Let us hope, therefore, that we have heard the last of "experiments" of this character. We express this hope the more devoutly since we have an uncomfortable idea that it will shortly be falsified.

As for the Leamington Station, we do not imagine that the termination of the contract with the Council—which has yet twelve months to run—will be followed by a stoppage of the works. In a town like Leamington the loss of two or three hundred street lamps ought not to be a serious matter. So far as we are aware—and we speak in part from personal observation—there is no fault whatever to be found with the design or the working of the station other than the insufficiency of the public lighting. It is worth noting that great satisfaction was given by the Sunbeam Lamps which were in use for a short time, but the expense was too great to permit of their continuance. How it came to pass that the experimental trials of arc lighting proved so unsatisfactory we cannot explain. It is unfortunate that Messrs. CHAMBERLAIN and HOOKHAM were unable to satisfy the no doubt somewhat fastidious tastes of the local big-wigs, but that arcs *can* be made to burn steadily is certain.

THE "Notes on the Design of Electric Motors" which were read by Mr. A. T. SNELL before the Old Students' Association at the Central Institute on Wednesday evening deserve attentive consideration on the part of all who are interested in this important branch of electrical engineering. It will be seen that Mr. SNELL maintains the view that although the comparison of dynamos and motors does not necessarily present any marked difference of design, yet in many cases a sound method does entail actual structural differences, even to the extent of producing a machine which, though good as a motor, may prove inferior or even bad as a dynamo. (Mr. SNELL does not, however, suggest, as certain flippant wits have phrased it, that the worse the dynamo the better the motor.) The point of departure which he recommends to be taken in the construction of a motor is *torque*, and not horse-power, whilst the speed is made a coefficient to determine the horse-power. The motor should, then, be designed so that the average maximum torque falls on a certain part of the characteristic, usually near the top of the straight limb. This can be attained by paying attention primarily to the armature alone, the field being designed at a later stage. The impressed E.M.F. is not an important factor in the general design. The factors by which the torque is determined are only in number—namely, the current, the number of wires on the outside and the resultant magnetic lines through the armature; but experience alone can show in what way these three factors can best be adjusted in order to fit the motor to the work for which it is intended.

PROJECTS for constructing an underground railway from the City to the West End by way of Holborn and Oxford-street have often been under consideration; but few of them have been so promising as the one which now occupies the field, and which not improbably will be submitted to Parliament in the ensuing Session. This is for an electric railway just below the surface of the roads, avoiding the main drains, and commanding easy access by a few steps from the footpaths. The scheme is threatened with a stout opposition on the part of the shopkeepers, but chiefly for reasons which would apply to all swift means of transit along their line of route. In constructing the subway room will of course be provided for laying electric light cables, as well as water-mains and gas-pipes, so that the scheme presents several collateral advantages. If properly engineered it should present every prospect of success.

THERE was once a German professor who, at the dinner of a learned society, gave as a toast "The Theory of Numbers, the only branch of Mathematics which can never be degraded to the service of Physical Science;" and at the next meeting of the society a Paper was read "On the Application of the Theory of Numbers to the Determination of the Nodes of Vibration of Thin Plates." This story may, perhaps, be paralleled in the history of the gyrostat, which no one would have supposed capable of lending itself to directly utilitarian ends. If there is any truth in the statement that it is capable of superseding the mariner's compass, probably the next information upon the subject will come from Mr. H. EDMUNDS; at any rate we are justified in denouncing that gentleman as the *fons et origo* of the rumour.

WE have received the following communication from a correspondent:—"The Electrolunatic presents his compliments to the Editor of *The Electrician*, and begs to inquire why at the Symphony Concerts at St. James's Hall they run the electric lamps, 170 in number, red-hot all the time that the gas is in full blaze; and whether the expense of the dozen horse-power thus wasted in warming the air of the hall falls on Mr. HENSCHEL or on the Grosvenor Gallery Company."

THE conflict between the Continuous and the Alternating Systems has been renewed with increased vigour in the States. In a long letter to the *New York Times* Mr. GEORGE WESTINGHOUSE, jun., makes some sharp comments on the recent experiments of Mr. HAROLD P. BROWN, at Edison's laboratory, Orange, N.J.; asserting that Mr. HAROLD P. BROWN is not seeking for truth, but is looking after the imperilled interests of the Edison Company. Mr. WESTINGHOUSE is not content that the alternating-current system should be considered as safe as its rival, it is much safer; "the alternating current is less dangerous to life, from the fact that the momentary reversal of direction prevents decomposition of the tissues." To this onslaught, Mr. HAROLD P. BROWN has replied by a challenge to a duel *à l'outrance*. Mr. WESTINGHOUSE is to take a current alternating 300 times a second through his body, and Mr. BROWN will do likewise with a continuous current; the pressure is to begin at 100 volts

Digitized by Google

and increase by 50 volts at a time; each contact is to be made for five seconds, and the battle is to go on until one or the other has cried enough. All this is, no doubt, excellent fooling, but has little or nothing to do with the question at issue, which is simply whether the dangers of high tension currents are so great and of such a nature as to warrant the enforcing of precautions which would practically amount to prohibition. This question, we take it, is satisfactorily answered by our own experience of alternating-current distribution from the Grosvenor Gallery, as well as by the enormous and increasing growth of the Westinghouse Company in America. Even Mr. HAROLD P. BROWN, we should think, must at heart accept the deductions he would have us draw from his experiments with several reservations, in the face of such a remarkable manifestation of public favour.

Sofia.—Plans and estimates are wanted for the lighting of Sofia by electricity. Proposals will be received by the Mayor up to May 1st.

Electro Harmonic Society.—In another part of our columns will be found the programme of the smoking concert of the Electro Harmonic Society.

Cardiff. — The whole of the electrical apparatus for the Christmas pantomime at the Cardiff circus has been supplied and run by Messrs. Sydney F. Walker and Olliver, of Cardiff.

Crompton and Co.'s Calendar.—A handy office accessory has been issued by Messrs. Crompton and Co. (Limited) in the shape of a combined blotter, calendar, diary, and address book.

"Electric Power."—We have received the first number of *Electric Power*, a new monthly journal, published in New York, and devoted to the interests of the electric railway, and of the transmission of power by electricity.

Swansea.—It is announced that the Swansea Harbour Trust, who have for some time lit the Prince of Wales Dock by electric light, are about to extend the system over the whole of the docks, wharves, warehouses, sheds, and offices under their management.

The Fire at the Melbourne Exhibition.—It is satisfactory to learn that the small fire which occurred in the Vienna court of the Melbourne International Exhibition, and which was at first reported to be due to an accident to an electric lighting lead, proves on further inquiry to have arisen from the use of a methylated spirit lamp.

Royal Society.—Dr. Gore read a Paper yesterday (Thursday) before the Royal Society on "The Relative Amounts of Voltaic Energy of Electrolytes;" and Prof. J. J. Thomson read a Paper on "The Resistance of Electrolytes to the Passage of Very Rapidly Alternating Currents, with some Investigations on the Times of Vibration of Electrical Systems."

The Metropolitan Board of Works.—The Metropolitan Board having been communicated with by Messrs Latimer Clark, Muirhead and Co., on behalf of the St. James and Pall-mall Electric Light Company (Limited), the clerk was requested to write to the company stating that the Board had no objections to the proposal of the company to lay electric lighting mains in Duke-street, St. James's, and certain other places in the neighbourhood. Permission was given to the London Electric Supply Corporation (Limited) to lay a main for conveying electricity through part of the Victoria Embankment Gardens east of Charing-cross Bridge.

The Anglo-Belgian Telegraphs.—The *Moniteur* recently published the Anglo-Belgian Telegraph Convention, which refers to the expiration of the concession to the Submarine Telegraph Company. No concession is to be granted to private persons. The two existing cables between Middelkerke and Ramsgate and La Panne and Dover are to be taken over by the two countries, and, if necessary, three new cables, each with four conducting wires, are to be laid. The rate for ordinary telegrams is to be 2d., or 20 centimes per word, and the returns are to be divided at the rate of 11·25 centimes for England and 8·75c. for Belgium. The sums received for transit telegrams are to be divided equally.

Electric Lighting at the House of Commons.—An extension of the system of electric lighting is in progress at the House of Commons. Hitherto the only portions of the building so lit have been the division lobbies and upper corridors, the library, reading room, tea room, smoke room, and a limited number of other apartments, but when the House re-assembles it will be found that gas has also been superseded in the cloak rooms and entrance lobbies, and on the main staircase. It is understood that this is the first step towards the general adoption of electric light at St. Stephen's, and that before long the oil lamps used in the committee rooms will be abolished, and electricity substituted for gas in the public corridors and waiting halls as well as in the members' lobby.

Obituary. — The death is announced of Sir William O'Shaughnessy Brooke as having occurred at Southsea, after a short illness. The late Sir William was born in 1809, consequently he was in his 80th year. He graduated M.D. at Edinburgh University, and subsequently entered the Bengal Medical Service as Assistant Surgeon in 1833, was appointed Surgeon in 1848, and Surgeon-Major in 1861. He was appointed Superintendent-General of Telegraphs in India in 1852, but resigned in 1862, and retired from the Indian Medical Service. He was the author of numerous works on scientific and engineering subjects, particularly one on the electric telegraph, published in Calcutta in 1839. He was knighted for his services in establishing the electric telegraph throughout India, and was a Fellow of the Royal Society.

The Thomson Effect.—M. A. Battelli has recently been pursuing some investigations with regard to the Thomson effect. The method employed was similar to that of Le Roux, but more accurate. These investigations show that, so far as the metals experimented on are concerned, the quantity of heat carried by the current is proportional to the strength of the current, and that, except for iron, it is proportional to the absolute temperature. If in the formula $\epsilon = a\,T\,i$, i is expressed in C.-G.-S. units, T in absolute temperature, and ϵ in calories, the value of the constant a for the different metals experimented upon will be as follows:—

Cadmium	$a = 3{\cdot}678 \times 10^{-8}$
Antimony	$a = 7{\cdot}081 \times 10^{-8}$
Bismuth...	$a = -3{\cdot}909 \times 10^{-8}$
German silver	$a = -2{\cdot}560 \times 10^{-8}$

Montreal.—The city of Montreal is supplied with the electric light by the Royal Electric Company, and a rather singular scale of charges is employed. For lighting residences the rates are—$8 per annum for first lamp, $7 per annum for second lamp, $6 per annum for third lamp, $5 per annum for fourth lamp, $4 per annum for fifth lamp, $4 per annum for sixth lamp, and $2 per annum for each subsequent lamp. The net effect of this sliding scale may be shown as follows:—5 lamps cost $2.20 per month, being an average of 50c. each; 10 lamps cost $3.42 per month, being an average 34c. each; 15 lamps cost $4.25 per month, being an average of 28c. each; 20 lamps cost $5.08 per month, being an average of 25c. each; 25 lamps cost $5.92 per month, being an average of 24c. each; 50 lamps cost $10.08 per month, being an average of 20c. each. Reception rooms are supplied with 16 candle-power, and other rooms with 10 candle-power lamps, no distinction in this case being made in the charges. But lamps of 16 candle-power are substituted for those of 10 candle-power where desired for $1.50 extra, and 25 candle-power for 16 candle-power for $5 extra per annum. The company have 425 arc lights, equal to 850,000 candle-power; also 20,000 incandescent lights in operation.

The New "Subject Matter of Patents" Index.—A correspondent writes:—"Who on earth is responsible for the idiotic subject-matter index of complete specifications advertised as accepted during 1888? It appears to be compiled with the express view and object of befogging and bewildering the unhappy searcher. Take any subject you like to search in—say, 'Incandescent Lamps.—Section II. of Electric Lamps.' Here is a copy: 'Filaments (including attaching to terminals), '87; 4,116, 4,549, 7,042, &c.' 'General Construction of, '87, 4,116, 4,549, 11,802,' and nine other numbers. 'Shades.—*See* Lamp

Digitized by Google

Shades.' Of what use, as an intelligible and useful index for searchers, is this? Every single specification under the number has to be turned up and examined. Absolutely no information is afforded, as used to be the case, as to whether a dynamo, a transformer, or a switch be included in the patent application. What unnecessary labour this system involves! Searching is a laborious business now; but what will it be in future years if this system is persevered with?"

Light Motors for Aeronautic Experiments.—M. Trouvé has constructed several small and extremely light motors of the Gramme and Siemens type, in order to carry out some aeronautic experiments. One of these motors, while only weighing 90 grammes, is capable of developing ·026 brake horse-power. All the parts of the machine are of aluminium with the exception of the magnets. This motor, which could be contained in a box of three centimetres side, is able to lift itself 22 metres in one second by means of a wire and a fixed support. A one horse-power motor constructed on the same lines would weigh barely 3·5 kilos. When furnished with a light screw and attached to the arm of a balance, the motor is able to lift its whole weight when connected to a constant source of electrical energy equal to 40 watts. In order to facilitate his experiments M. Trouvé places his motor at one end of a long lever capable of vertical and horizontal movement about its centre, the electrical connections being made with the motor through the lever and its supports.

The Telephone in Switzerland.—The returns published by the Swiss Confederation with reference to the development of telephonic communication in Switzerland show that, since the establishment of the first telephone in 1880, sixty-one towns have been provided with it, and there are now 6,944 telephonic stations, of which no fewer than 1,500 are in Geneva and its suburbs. Most of the Swiss towns are now connected with one another, Geneva communicating not only with Lausanne and other places on the shores of the lake, but with Berne, Zurich, and St. Gall. The Confederation has taken over the telephones, which are attached to the Department of Posts and Telegraphs, and the annual cost of subscription is only £6. Notwithstanding this moderate charge the receipts exceed the expenditure by about £8,000, and the Federal Council now contemplates reducing the rate of subscription to £5 for the first year, £4 for the second, and 80f. for the following years, with a trifling supplemental charge for those subscribers who use the instrument more than 500 times during the twelvemonth.

Westminster.—At a meeting of the St. Margaret's and St. John's (Westminster) Vestry, the Works and General Purposes Committee reported that they had before them a proposal by the Kensington Court Electric Lighting Company, offering, with a view to the general adoption of electricity in place of gas in the more important thoroughfares of the Knightsbridge district, to light up the lamps at Hyde Park Gate for one month free of charge, after which period they would be prepared to enter into an arrangement for the permanent supply of current to these and other lamps which the Vestry might decide to have so lighted. The cost of the lighting would be based on the experiment. The committee recommended that the application be granted, subject to the company holding the Vestry harmless against any loss or expense, and on the direct understanding that they were not committed to the continuance of the light. Provision should also be made for the company to light the gas in the lamps in the event of the electricity failing. The report and recommendation were agreed to.

Wrought-Iron Belting.—Mr. John Spiers, of Worcester, Mass., gives the following interesting particulars of the successful adoption of wrought-iron belting:—"A lathe used for turning rolling-mill rolls, compound gear, has a 48in. pulley. This is driven by an 18in. pulley on the countershaft, which makes 120 revolutions per minute, and is 8ft. from the 48in. pulley, measured from centre to centre. Both pulleys are of iron smoothly turned on the faces. A 7in. double leather belt was used in these pulleys, but would slip when the turning tool became dull. This belt was replaced by one made of Russian sheet iron, the same as that used for stove-pipes and parlour stoves, and was riveted together in the ordinary way. It was 7in. wide and 2in. longer than the leather belt the extra length making up for the want of elasticity in the iron. During one year's steady run this iron belt could not be slipped, even when a heavy cut on a 25in. roll was taken, which broke a Sanderson steel tool, having a section of 12in. by 2½in., a cutting surface of 2½in., a feed of ⅛in. per revolution, and an overhang of 4in."

The Electric Light at Leamington.—The Leamington Town Council resolved on the 14th inst. to give the Midland Electric Light Company twelve months' notice to determine the contract for lighting the streets of Leamington by electricity on the ground that it had been a failure. Two months ago Messrs. Chamberlain and Hookham initiated experiments with 36 candle-power incandescent lamps, the "Sunbeam" and the arc system. The last-named, though the cheapest, has been dismissed owing to the flickering and unreliable nature of the light. Nothing is said against the "Sunbeam" lamp but its expense, as it would entail an annual outlay of £900 for lighting the principal streets of the borough. The gas company offer to light the same area with Sugg's "Whitehall" lamps for £300 per annum. The local papers say that the townspeople very much regret that the spirit and enterprise displayed by Messrs. Chamberlain and Hookham has not been attended with better success, and do not relish the prospect of having to go back to gas—a necessity which seems forced upon them by economic considerations.

Morecambe.—At a meeting of the Morecambe Local Board the clerk said he had received a letter from Mr. Darlington, solicitor, Bradford, on behalf of Messrs. Andrews and Preece, asking whether the Board proposed to oppose their application for a Provisional Order to supply electric lighting within the district. A gentleman handed him (the clerk) a notice on 29th October, stating that on the expiration of six weeks the promoters intended to apply for the order, but according to Act of Parliament the notice must be given in July, and all advertisements issued in October or November. It was impossible for anything to be done under that notice. It was also quite clear that the Board would not assent to an application before they saw plans and particulars of the scheme. In the short discussion that followed the Chairman remarked that the Board were and had been for some time considering the question of supplying electricity themselves. He thought the manner of the present application rather a singular one, and that it looked as if it was not a very strong company. It was ultimately decided that until plans and particulars of the scheme were submitted the Board could not take any action in the matter.

Electricity in Mines.—At the Veteran Mine, near Aspen, Col., there is a complete electric installation, driven by a water-power generating plant. A Pelton wheel is operated by water from a flume 70ft. above, the flume being 20in. diameter, with a 3in. discharge nozzle; the volume of water thrown against the wheel is regulated by a governor, according as the strain is given or slackened by the engineer a mile and a quarter distant A 500-volt dynamo is used, and a Sprague motor of 10 to 15 horse-power. The motor is located in a chamber 1,000ft. long in the mine. The engineer has the usual brake on the hoister ready to his right hand, while with his left he turns a small switch to start, stop, or reverse the motor, or to regulate the speed. In addition to the hoist, the motor pulls in the loaded or empty cars, and controls the speed of all the trains on the tramway and in the tunnel. The entire train is sent out and returned in eight minutes, and twenty cars can be handled rapidly and continuously if necessary. The motor utilises about seventy per cent. of the power from the water wheel. The working is very economical, and there is no trouble from noise, &c., with the motor in the tunnel. This plant has been in use for some months, and a duplicate plant is to be put to work extensions of this mine and the Franklin Mine.

Electric Meter Competition in Paris.—The following are the terms of the electric meter competition, which is to take place under the auspices of the Paris Municipal Council:—1. The instruments submitted to the committee may be either for continuous or alternating currents. Generally speaking every instrument will be admissible which is intended to measure electric energy under any form whatever. 2. The competitors

Digitized by Google

may suppose that only the difference of potential or the strength of the current is varied, or that both are varied. They may therefore send in ampere-hour meters, volt-hour meters, or watt-hour meters. 3. The meters must, above all, be suited to a small consumption; they ought to be able to measure the energy furnished to a single 10 candle-power lamp. 4. For alternating currents, the same conditions hold good; but attention should especially be given to the construction of watt-hour meters, which alone give exact results in inductive circuits. 5. The instruments will be submitted to comparative tests as to (*a*) proportionality and accuracy at every output; (*b*) the energy wasted in effecting the measurements; (*c*) the disturbance caused by using the instruments; (*d*) the practical value of the instruments (simplicity, cost, regulation). The five members of the jury appointed by the Municipality are MM. Mascart, Hospitalier, Vaillant, Lyon-Alemand, and Pottier.

Strand District Board of Works.—At the last meeting of this Board the Lighting Committee reported that they had considered applications for Provisional Orders from the Metropolitan Electric Supply Company (Limited), London Electric Supply Corporation (Limited), House-to-House Electric Supply (Limited), Electrical Power Storage Company (Limited), and from the Westminster Electric Supply Corporation (Limited). They (the committee) considered that the two first-mentioned companies only were in such a position as would render it prudent for the Board to enter into negotiations with a view to one or other, or both, of such companies supplying electricity to the district. The first-named company, the Board, by the adoption of one of the reports of the committee, had already viewed with some favour; but with reference to the second, it appeared to feel strong enough to carry the Provisional Order it had launched, and therefore was not prepared to make any arrangements with or concessions to the Board. They recommended, however, that the clerk should be directed, in conjunction with the Parliamentary agents, to present objections to the Board of Trade against the granting of Provisional Orders to all the above-mentioned companies. Dr. Sandwell, in moving the adoption of this report, said it was only a preliminary report of the committee, who would further consider the matter in the course of a few days. The report and recommendations were adopted.

A New Method of Tracing Curves by Photography.—In a recent number of the *Bulletin of the Académie des Sciences de Belgique*, M. Eric Gérard describes a new method of automatically registering observations by means of photography. In some of his researches into the nature of alternating currents, M. Gérard obtained very good curves by using a delicate dead beat galvanometer. A beam of electric light was reflected from the galvanometer mirror through a lens, falling finally on to a sheet of sensitive paper. After some trouble very good results were obtained in this way, but not being completely satisfied, he cast about for some other method of obtaining the same end. M. Gérard's new arrangement consists of a moderate-sized Ruhmkorff coil, the spark from the secondary coil of which plays between a piece of aluminium wire and the point of an arc lamp carbon. The two electrodes are fixed at least one millimetre apart. The spark is projected on to the movable mirror, and thence to the sensitised paper, which may be wrapped round a drum, or, more conveniently, simply stretched on a frame, which can be allowed to fall between guides. The period of the sparks depends solely on the elasticity of the spring of the vibrator of the primary coil, and the number of spots photographed in unit length of the curve on the sensitised paper forms a convenient time scale. By connecting the electrodes of the secondary coil to a couple of small Leyden jars, a very short and white spark is obtained, the position of which is invariable. This plan has the advantage of reducing the dimensions of the numerous spots which make up the curve photographed.

Italian Telegraph Statistics.—On the 30th June, 1887, the length of the Italian telegraph lines amounted to 32,768 kilometres, the length of wire being 113,046 kilometres, an increase over the preceding year of 2,195 and 4,138 kilometres respectively. The offices opened for the service of the public during the period 1886-87 were 244, of which 160 are worked by the Administration, and 84 by the railway and tramway companies. The total number of offices open for the service of the public on the 30th June, 1887, was 3,374, of which 2,192 were Government and 1,182 railway or tramway offices. The apparatus in use in the Government offices increased during the year by 210, reaching a total of 3,485. The number of inland and foreign telegrams dealt with in the period 1886-7 was 8,844,015, an increase of 510,716 compared with the period of 1885-6. The private inland telegrams forwarded both by the Government offices and by the railway offices were 7,024,614, showing an increase of 333,226 over the preceding period. Forwarded and received foreign telegrams increased in 1886-7 by 148,365, reaching a total of 1,492,215. As for Government telegrams, the total of the previous year was slightly increased. The ordinary receipts of the Administration were 13,888,670 lire (£555,547); and the ordinary expenditure 11,113,053 lire (£444,522). The net profit was therefore 2,775,617 lire (£111,025). This profit would be reduced to 1,125,881 lire (£45,035), if we deduct the value of the chargeable Government telegrams, which amounted to 1,649,736 lire (£65,989). The total value of franked Government telegrams would have been 811,286 lire (£32,451), and was less by about one-sixth than that of the preceding period, 1885-6.

Barney's "Make and Break" Telephone.—From a pamphlet which has been sent us by Mr. W. C. Barney we extract the following description of his improvements on the Bourseul telephone. We may add that Bourseul's instrument was referred to in the judgment of the Supreme Court of the United States (*The Electrician*, April 6th, 1888, p. 609) in terms which leave it to be inferred that the principle is outside the Bell patent. Mr. Barney describes his latest telephonic achievement as follows:—"These instruments are very simple improvements on instruments invented by Bourseul. The description published in 1854 is in the following words:—'Suppose a man speaks near a movable disc sufficiently flexible to lose none of the vibrations of the voice, at each of the vibrations the disc touches a small point placed in front of it, and this contact suffices to throw the current into the line. The improvement consists in placing a point on each side of the disc so that the contacts will be made at each half vibration of the disc, instead of at each full vibration, as in Bourseul's transmitter. Bourseul's receiver is described in the following words:—'At the extremity of the line the current enters an electromagnet, which attracts another vibrating disc of size and quality identical with the former; attracted and repelled very rapidly, exactly, and as rapidly in fact as the disc above mentioned, this second disc gives forth a sound, which will have the same musical value as that of the other disc, as the number of the vibrations per second is the same in both cases.' The improvement consists in substituting for the soft iron core of the electromagnet a steel core magnetised. The Supreme Court of the United States says:—'The method of Prof. Bell consists in creating changes of the intensity of a continuous current or flow of electricity in a closed circuit.' Barney's system consists in the use of intermittent pulsations of electricity in contradistinction to undulatory currents, whereas Bell's system, the Supreme Court says, 'consists in the employment of a vibratory or undulatory current of electricity in contradistinction to a merely intermittent or pulsatory current.' Numerous crucial tests by eminent practical scientists, made solely in the interest of science, have demonstrated that when the circuit is closed on the right-hand side, varying from the most delicate contact to a firm contact, no sound whatever can be heard in the receiver, and when the circuit on the left-hand side is closed with a delicate contact, a series of ticks only is heard; and when the circuit is closed firmly no sound is heard in the receiver; and when both circuits are closed at the same time, varying from the most delicate to a firm contact, no sound is heard in the receiver; when the electrodes are not in contact articulate speech is reproduced in a clear, loud, and distinct tone. It is, therefore, evident that Barney's instruments do not operate with an undulatory current in a closed circuit, which is the essence of Bell's system." The improvements described were patented by Mr. Barney in the United States on February 8th, 1887, and August 21st, 1888."

NOTES ON ELECTRO-MAGNETIC INDUCTION.

BY DR. J. A. FLEMING, M.A.

(Continued from page 272.)

The screening action of metallic masses has been well demonstrated in certain investigations by Prof. D. E. Hughes in carrying on some highly valuable experimental researches into the means of preventing induction upon lateral telegraph wires.* It has many times been proposed to annul mutual induction between telegraph and telephone wires by covering them over with thin metal covering, which covering is kept "to earth." It is now known, and well exemplified in Prof. Hughes's experiments, that this shielding affords no protection when the covering is not very thick and when the rate of change of the currents is not very rapid. A gutta-percha wire was enclosed in ten coverings of tinfoil, and such arrangement was not found to afford protection to induction, as detected by a telephonic wire stretched alongside. Even when twenty coatings of thin charcoal iron were put round the wire, not only was there found to be a very sensible permanent field outside the iron, but changes of field were made manifest also. It is not to be taken that these experiments invalidate the fact of magnetic screening, but only that the low conductivity of the envelopes used is ineffective at the speed of current change employed to render visible the effect of magnetic screening. It is different, however, if the inductive effects are being produced by a *very rapid rate* of change of field. For suppose that a small circuit as before is placed in a uniform field, and traversed by q lines of induction due to this external field. Suppose q varies according to a simple periodic law, so that $q = \mathrm{Q} \cos p t$, where $p = 2 \pi n$, n being the frequency of the alternations. Then we have

$$-\frac{dq}{dt} = \mathrm{Q}\, p \sin p t\,;$$

but $-\frac{dq}{dt}$ is the value of the impressed electromotive force in the circuit, and if we call the current at any instant i, then, by the principles in Chap. III., we have

$$i = \frac{\mathrm{Q}\, p}{\sqrt{\mathrm{R}^2 + p^2 \mathrm{L}^2}} \sin (p t - \theta),$$

in which R is the resistance and L the inductance of the circuit, and

$$\theta = \tan^{-1} \frac{\mathrm{L}\, p}{\mathrm{R}}.$$

Suppose that R is very small compared with $\mathrm{L}\, p$, which is the case when n or the frequency of alternation is made very great, then R vanishes compared with $\mathrm{L}\, p$, and if we call i'' the value towards which i approximates in this case, we have

$$i'' = -\frac{\mathrm{Q}}{\mathrm{L}} \cos p t,$$

and

$$\frac{di''}{dt} = \frac{\mathrm{Q}}{\mathrm{L}} \sin p t,$$

or

$$\mathrm{L}\frac{di''}{dt} = \mathrm{Q} \sin p t = -\frac{dq}{dt}.$$

Hence

$$\mathrm{L}\frac{di''}{dt} = -\frac{dq}{dt},$$

or

$$\mathrm{L}\, i'' + q = \text{constant}.$$

Hence the field due to the current in the circuit, together with the external field, is a constant quantity, and we get the condition of perfect shielding. We may sum up the foregoing by saying that if a screen of absolutely no electrical resistance is interposed between a primary and secondary coil, it effects a perfect magnetic screening, whatever may be its thickness. If, on the other hand, the screen has a finite conductivity, then the screening will be very imperfect, unless a very great thickness of material is used, and the above will be true when the change of field or the change of primary current is a simple "make" and "break" or a slowly periodic change. When, however, the change of current in the primary is *very* rapidly periodic, then the screening effects of even imperfect conductors will make themselves felt, and a comparatively thin screen of metal will effect a nearly perfect shielding for induction. This theory is strikingly confirmed by some very beautiful experiments of Mr. Willoughby Smith, which are described in the *Journal* of the Society of Telegraph-Engineers (November 8, 1883, Vol. XII., p. 458), and entitled "Experiments on Volta-Electric Induction." Mr. Willoughby Smith's apparatus consisted of two flat coils A and B (*see* Fig. 21), placed a certain distance apart. One of these was a primary coil connected with a battery, and the other was connected with a sensitive galvanometer. In the circuit of both were current reversers, which reversed the galvanometer and battery alternately, and hence made the

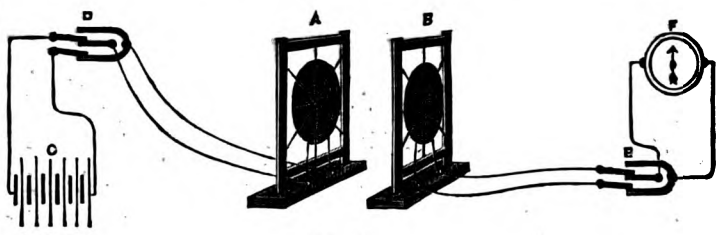

Fig. 21.

opposite induced currents both affect the galvanometer in the same direction. This being arranged, the commutator was started so as to reverse the currents very slowly, and a sheet of copper interposed between the spirals. Under these circumstances the interposition of the copper produced but little effect. If, however, the commutator was driven at a very rapid rate the copper plate caused a marked diminution in the galvanometric deflection, and this diminution was greater in proportion as the speed was greater. For the original Paper a curve is given (Fig. 22) which shows the decrease in the galvanometer deflection, expressed as a percentage of the original undiminished deflection, corresponding to various

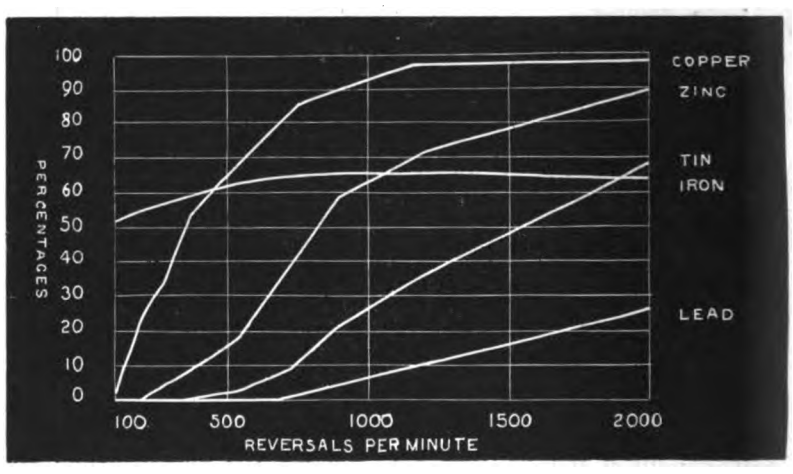

Fig. 22.

speeds of reversal. It will be seen that the *less* the conductivity of the metal the *greater* must be the speed in order that the magnetic screening may approach perfection. Iron, of course, occupies an exceptional position. It cuts off, even at very low speed reversals, a large portion of the field, not by a true screening action, but by conducting away the lines of magnetic force and preventing their access to the secondary coil. It will be seen that at any given speed the order in which the metals reduce the deflection is the order of their electric conductivity, and that as far as the diagram goes the lines all (except iron) slope upward, indicating that at very high speeds the screening of even the worst conductors will approach perfection. It would no doubt be found that if

* *See* a Paper by Prof. Hughes "On Lateral Induction in Telegraph Wires," read before the Soc. Tel. Eng., March 12, 1879.

the telephone were used as a detector that the magnetic screening of a copper plate or thin tinfoil sheet would become very manifest for high notes when not in any way marked or distinguishable for notes or sounds of low frequency of vibration.*

As far back as 1840 Dove had made experiments† on the effect of the introduction of cores of various materials into the primary circuit of an induction coil. His apparatus consisted of two similar primary bobbins wound on tubes of non-metallic substance and connected in series (Fig. 23). Over each primary bobbin was wound a secondary circuit, and these secondary circuits were connected in series, but so that the induction of the two primary bobbins operated in opposite directions and nullified on the whole secondary circuit each other's effect. Exact neutralisation was obtained by adjusting one of the secondaries. When this was the case various cores of iron rods of different kinds were inserted in one primary bobbin, and it was found that the induction balance was destroyed. By inserting iron wires of a certain size in the other core, balance could be again obtained, but not simultaneously, as estimated by the galvanometer and by the shock. Thus, with a bar of forged iron 110 wires had to be inserted in the other coil to obtain an equilibrium, as estimated by the galvanometer; but as far as could be judged by the shock 15 wires were sufficient. With regard to different kinds of iron, experiment shows that if we class them according to galvanometric effect we obtain a different series to that at which we arrive when classifying them in the order in which they create sensation by shock. Thus grey rough cast-iron is the kind which approached nearest to bundles of soft iron wire in respect of increasing the shock. Enclosing iron wires in a brass tube reduced the action of the wires in disturbing the inductive balance and rendered them very little better than a bar of solid iron. When the primary current was a discharge from a Leyden jar, Dove found that the physiological effect (shock) of the secondary current, as estimated, was reduced by the introduction into the primary bobbin of non-magnetic conducting cores; in other words, the introduction of a core of non-magnetic but highly conducting material into the primary bobbin reduced the power of a primary discharge to create a secondary discharge. These last results may be obtained in a more modern form by the substitution of a Bell telephone, to detect the tertiary currents generated by the metal core.

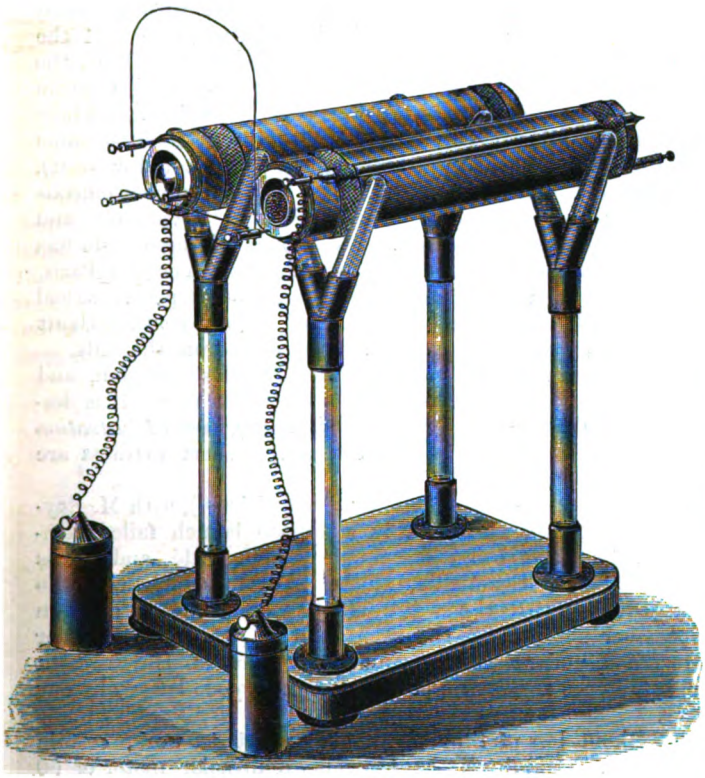

Fig. 23.

Let a Bell telephone be connected in series with the secondary coil of a small induction coil, of which the primary is wound on a hollow bobbin, and the frames are wholly of wood or non-metallic substance. A convenient form is that known as Du Bois-Reymond's sliding coils. Let an interrupter in the primary circuit make and break the circuit rapidly. This being so, the telephone emits a steady rattle or hum. If a massive copper rod is introduced into the primary bobbin as a core, the telephonic rattle is more or less suppressed; if a core of soft iron wires is introduced the noise is increased; if a core of solid iron or steel is used the noise may be increased, but not so much as when the divided iron is used. The explanation of the exalting effect of the soft iron wire is simple. The presence of the iron reduces the "magnetic resistance" of the circuit of magnetic induction due to the primary current. More lines of induction therefore flow through the secondary circuit, and hence the strength of the secondary current is increased, and the rate of change of induction through it is also increased. The diminishing effect of the copper core is explicable by the light of the knowledge that in such a conducting core the primary current generates induced currents, and these in their turn re-act upon the secondary circuit, inducing in it a tertiary current. The direction of the currents induced by the primary in the solid core and in the secondary circuit are the same. The direction, however, of the first half of the tertiary current developed in the secondary by the current in the copper core is opposite to the direction of the current developed in the secondary by the action of the primary. Hence it results that the

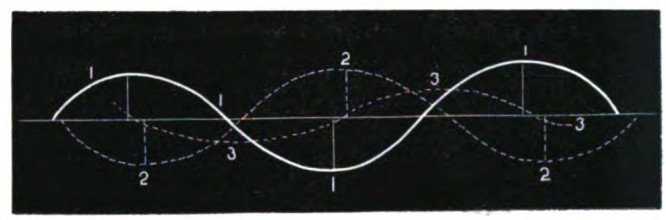

Fig. 24.

current in the secondary circuit is more or less wiped out by the opposing inductions due to the primary circuit and the currents induced in the copper core. Otherwise the operation might be regarded thus:—Suppose the primary circuit to be traversed by a periodic current creating a simple periodic flux of induction through the copper core. As we have seen under the head of magnetic screening, this variation of induction would induce currents in the copper core which would themselves generate a flux of induction, which would, if the conductivity of the core were perfect, or the rapidity of change of induction infinite, be exactly equal and opposite at each instant to the flux of induction producing those currents.

If the conductivity is not quite perfect, or the rate of variation not very great, yet nevertheless the direction of the field of magnetic force inside the copper, due to the currents induced in its mass, will more or less oppose the field of force at every instant which is by its fluctuations generating those currents. If the thick line 1 1 1 in Fig. 24 represents the sinusoidal or simple periodic change of induction or magnetic field in the interior of the copper, due to the primary helix, and if the dotted line represents roughly the changing field due to the eddy currents generated in the core, which are nearly 180° behind the primary in phase, the integral or sum of both superimposed fields at any instant is less than the original one due to the primary alone at the corresponding instant. Also the *mean rate of change* of the resultant field is less, and the secondary circuit experiences at every instant a less inductive electromotive force. The same reasoning which we have employed in the case of magnetic shielding applies here, and the differences in the reducing effect of cores of various metals would be found to be less at high speeds of

* The above explanation of the cause of the difference between the screening of the different metals is not that given by the distinguished investigator, but it is the explanation which to the author seems most in accordance with known principles.

† Dove, Poggendorff's *Annalen*, Vol. XLIX., 1840

Digitized by Google

alternation than at low. In some small induction coils used for medical purposes the strength of the secondary current is graduated by drawing in or out of the primary coil a copper tube which slips over the bundle of fine iron wires used as a core. The *rationale* of the action of this copper tube in so operating is in a rough general way to be found in the principles laid down above.

(To be continued.)

ALKALINE ACCUMULATORS AND THE "GYMNOTE" SUBMARINE TORPEDO BOAT.

BY P. B. ELWELL.

To invent a reversible couple, or secondary battery, with iron, copper, or carbon plates in an alkaline solution has been the aim of many electro-chemists ever since Planté gave to the world, in his modest, unostentatious way, the first so called accumulator. The advantages of a light and strong metal for the plates, a solution nearly neutral when in a state of discharge (for transport at ordinary rates), and non-injurious to adjacent metal work, having no fumes of any kind, and the use of sheet iron cell, or tin box, being alone of sufficient attraction, without considering the possibility of attaining a higher rate of discharge without injury and a greater amount of energy stored per pound of cell.

But, although many attempts have been made, nothing of any practical value appears to have been reached until, in 1886, a French engineer, M. Dezmazures (who, together with his chemist and electrician, M. Commelin and his associates, MM. Virloy and Bailhache, had been trying all possible combinations with more or less—but never any complete—success, mainly for want of a negative plate that would freely absorb the oxygen of the charge and give it back in the discharge), bethought himself of first obtaining *a perfectly non-coherent mass of pure metallic copper* by electrical reduction from the oxide, and then compressing it in a steel mould to the extent of some thousand atmospheres by means of a hydraulic press.

On immediately carrying out this idea they found that by nothing but an enormous pressure it was easy to make a pure copper plate of equal strength and hardness to rolled copper from the loose reduced metallic "mud." Then, by regulating the pressure so as to produce an *apparently* solid copper plate, but in reality of only about two-thirds the specific gravity of rolled copper, and consequently *infinitely porous*, a beautiful negative plate was produced. I use the term "beautiful" in a literal sense, for every one who sees these plates with their planished surface of shining copper cannot but admire them. This plate was found to possess the properties required—perfect depolarisation and very low electrical resistance. It was then only a question of finding a suitable solution from which a metal could be alternately deposited upon the positive plate and redissolved.

Research having already been made in this respect, it was an easy matter to test the most favourable results in combination with the new negative plate, and the following general construction has been finally adopted, with certain modifications when used for special purposes. A copper negative 2 to 3 millimetres thick, enclosed in an envelope of parchment cloth (ordinary parchment paper being liable to get torn by rough handling), opposed to an iron positive plate of wire gauze, in a solution of zincate of potassium of 50deg. Beaumé, the whole contained in a thin sheet-steel tinned box. An extremely strong light and serviceable cell is thus obtained. During the charge the zinc is deposited upon the iron gauze plate and the superfluous oxygen is absorbed freely by the copper plate. In the discharge the zinc is re-dissolved, combining again with the oxygen from the copper plate. It will be thus seen that there is no reason why the plates should in any way suffer, and it is found, after the considerable experience referred to below, that whilst the iron plates remain absolutely unchanged, the copper plates actually become harder and stronger by long use.

These cells give a comparatively low E.M.F. and a very large quantity of current, and where small "quantity" only is required the cells may be made up in cases of three, one of such boxes measuring 10in. by 4½in. by 10in. (high), and weighing 28lb, giving a discharge of 150 ampere-hours, at from 2·70 to 2·05 volts, according as the rate of discharge be slow or rapid. This division into three cells for each box is very favourable in preventing "swilling" where much knocked about.

A discharge may be made in as little as 2½ hours with fair efficiency and perfect safety to the plates, and for sudden efforts —such as are required for tramway work—a current of 200 amperes may be obtained without injury from a cell weighing 19lb. (This was actually shown by Messrs. Sautter, Lemonnier, of Paris, when they kindly lent a battery of these cells to the Académie des Sciences for illustrating the "Cowles" aluminium process.) The cell may be completely sealed up for portable work, and when used for stationary purposes the solution may be covered by a film of oil to prevent the formation of carbonate and "creeping" up the terminals.

The notice of the French Government experts was early drawn to this invention, and in the Spring of 1887 a battery of 132 cells, weighing 40 pounds each, was ordered for a large steam launch. This launch was thoroughly tested at Havre in the following months of September and October, with the result that the naval authorities ordered a large battery of 560 of the same cells (9¾ tons) for the new submarine torpedo boat, the "Gymnote," then being designed by M. Zédé and Captain Krebs. (Meanwhile a few tests were carried out in London, where an electric omnibus was driven by 14cwt. of these cells at the same speed as 28cwt. of the most approved lead cells could drive it). This battery was tested at Havre by the Government officials previously to its installation on board the "Gymnote," and accepted as most satisfactory. An account of these tests was read by M. Mascart, before the Académie des Sciences at Paris, and showed a total weight of 37 kilogrammes per electrical horse-power-hour, and an efficiency of 65 per cent., without including a residual charge afterwards taken from the cells.

The "Gymnote" was not launched until last autumn, and the trials did not take place until a few weeks ago. It is described in *La Nature* (December 22nd, 1888), and *l'Illustration* (December 8th, 1888), from which a few short extracts are translated as follows:—

"A first attempt, in November, 1876 (? 1886), with M. Reynier's accumulators installed in a torpedo launch failed completely. Without being discouraged, MM. Zédé and Krebs applied to MM. Commellin, Bailhache and Desmazures, who had just invented the light alkaline accumulator, and on September 20th, 1887, the same boat in which M. Reynier had failed, underwent the triumphant trials at Havre which resulted in the acquisition of the electric torpedo launch by our navy.

"Without loss of time the engineers set to work, certain of success. Captain Krebs built his multipolar motor of 60 horse-power. M. Zédé entrusted M. Romazzetti, Naval Constructive engineer, with his plan of the 'Gymnote,' which was laid down in the Toulon Arsenal, and MM. Commelin and Desmazures proceeded with the construction of the giant battery of 564 accumulators, to have a capacity of 93 million kilogrammetres (345 horse-power-hours). The much-regretted M. Desmazures died very suddenly last January, but M. Commelin, assisted in a patriotic manner by Madame Desmazures, was well able to finish his part of the work. The 'Gymnote' is propelled by a powerful 4-blade screw 1·50 metre in diameter. The motor is Captain Krebs' invention. It has 16 poles arranged round a ring armature one metre in diameter, furnished with a commutator and four brushes, two for going ahead and two astern.

"The speed is 200 revolutions per minute, and the propeller is driven directly. The motor weighs 2,000 kilogrammes and gives 60 horse-power with the normal current of 220 amperes at 220 volts.* The electrical energy is provided by the battery of 564 alkaline accumulators, completed by M. Commelin. Each

* This is the French cheval-vapeur = 735 watts, and the armature resistance only has apparently been allowed for. The *actual* efficiency at *200 revs.* does not exceed *80 per cent.*

Digitized by Google

cell weighs 17·5 kilogrammes, making a total weight of 9,840 kilogrammes. Taking the total capacity of 345 horse-power-hours, the weight per horse-power-hour stored is 28·6 kilogrammes. This allows for a speed of 10 knots for six hours.

"The trials at Toulon were begun in the Vauban Dock, and continued in the open sea. They surprised, beyond measure, the few privileged spectators. The boat manœuvered like a fish, on the surface as well as below, and maintained the desired depth with precision at all speeds, changing direction, and taking up the position ordered, with great facility. We cannot speak too highly of the complete success which has crowned the efforts of MM. Zédé, Krebs, Commelin and Romazzetti, who may be proud of their work."

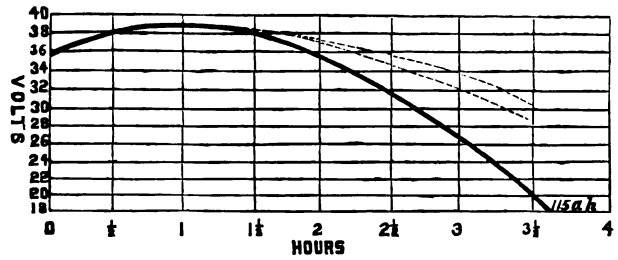
But the most favourable and important field for the use of these cells—where the very shaking to which they would be subjected would be most advantageous—is the traction of tramcars and vehicles of all kinds running on paved roads. For this purpose, the lightness, strength, and durability under great varieties of discharge, coupled with absence of fumes to corrode machinery, are a very great consideration, and steps have already been taken with a view to using the accumulators on the Paris Tramways, where something will probably be done in time for the opening of the Exhibition.

"Diagram of Two Discharges.

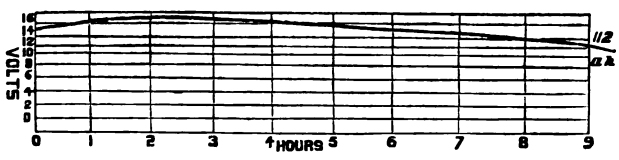
Cell measuring 6 inches by 3¼ inches by 6 inches outside.

Weight of box and solution	6lb.
Total weight of plates, copper and iron	3 ,,
Total weight of cell	9lb.

"Charge: 10 amperes for 12 hours at 1 volt (average E.M.F.), solution zincate of soda 45deg. Beaumé. Discharge through a constant resistance of ·0017 and ·0066 ohm respectively. These figures are to be considered approximate only, the measuring instruments not being so delicate as could be desired, but as one of the first experts of the day is about taking exact tests such data will soon be available.



The dotted lines give an idea of the improvement caused by agitation of the solution during discharge.



"The above diagram shows two idiosyncratic curves of discharge, one at a very high rate and the other at a normal rate. The peculiar rise in E.M.F., especially remarkable in the case of the heavy discharge, may be accounted for partly by the decrease in internal resistance caused by the solution rising in conductivity as it increases in density and partly by the rise in temperature having a similar effect, much more noticeable in the curve of rapid discharge.

"The great question of a perfect miner's lamp has occupied the attention of those connected with this new accumulator, and by substituting a thin plate of silver—made by the same process—for the copper plate, an increase of about 100 per cent. is obtained in E.M.F. Consequently, the "silver cell" only weighs about half the copper one for a given output.

"For a miner's lamp the battery with silver negative plates only weighs 3lbs. for 50 watt-hours, and of this weight not more than ½lb. would be silver—always preserved in its metallic form, with no waste or deterioration in value—the cost of which is thirty-two shillings; but as the process of manufacture actually raises the value of the metal by purification (it is the same in the case of copper, and a point of great importance), this outlay in silver is not a costly matter, 4 per cent. per annum covering wear and tear, depreciation and interest."

THE INSTITUTION OF ELECTRICAL ENGINEERS.

SIR WILLIAM THOMSON'S PRESIDENTIAL ADDRESS.

The Institution met on Thursday last at the Institution of Civil Engineers, the retiring president, Mr. E. Graves, at first occupying the chair.

After formal business had been transacted,

Mr. Graves announced that the last legal steps had been taken in reference to the name of the Society, and that in future "The Institution of Electrical Engineers" would take the place of the old name in all documents.

The Secretary (Mr. Webb) then read the following letter from Prof. Silvanus Thompson, to whom had been awarded the Society's premium:—

"20, Arundel-gardens, 15th December, 1888.

"Dear Mr. Webb: I am in receipt of yours of the 14th inst. announcing that the Council of the Society of Telegraph-Engineers and Electricians have awarded to me the Society's "Premium" for 1888. I need not say that I gratefully acknowledge the honour which the Council have done me in selecting me to be the recipient of this award. I should value highly such an addition to my library, and deeply appreciate the expression of the Council's goodwill.

"That the original intention of the Society in establishing this premium was to offer it for the encouragement of the efforts of the junior members of the Society is, however, obvious.

"And I, having already once served on your Council—namely, in 1886—and having just been again elected, cannot but feel that, though technically I may be entitled to the honour, the interests of the Society will be best served if the Council will revert to the original intention of the award.

"I therefore ask the Council to allow me most respectfully to decline the premium.

"Believe me, dear Mr. Webb,

"Yours very truly,

"Silvanus P. Thompson."

Mr. Graves said they could hardly fail to appreciate Prof. Thompson's motives (hear, hear). The recommendations of the Premium Committee of the Council were that that gentleman having declined to receive the prize awarded to him, the gentleman named for the second prize should receive the first, the gentleman named for the third should receive the second, and the gentleman who was highly commended should receive the third (applause).

Mr. Graves then presented the first and second prizes to Mr. A. C. Cockburn and Mr. Edward Stallibrass respectively, and stated that as Mr. E. O. Walker, to whom the third premium had been awarded, was in India, his wishes as to the form in which he desired to receive it had not, of course, been yet ascertained.

The retiring President then vacated the chair in favour of

The President (Sir William Thomson), who was received with loud applause.

Sir Wm. Thomson then delivered the following Presidential Address on

"Ether, Electricity, and Ponderable Matter."*

Gentlemen: My first duty is to give you my warmest thanks for the great honour you have done me in electing me to be the first President of the Society of Electrical Engineers. Fourteen

* As Sir William Thomson has been good enough to undertake the revision of our report, we are in a position to publish only the first portion in the present issue

Digitized by Google

years ago, when the three-year-old Society of Telegraph-Engineers honoured me by appointing me to be their President, the Society numbered 570 members; it now numbers 1,550 (hear, hear). It is gratifying to us to think how that young Society has grown and how successful it has been.

But while we think with pleasure of the great increase of our numbers, that pleasure is saddened by the thought that a great many of the old members, are gone, and especially the first two presidents—Sir Wm. Siemens and Mr. Frank Scudamore. The genial presence of Sir Wm. Siemens is a happy recollection to many of us—I think I might say to nearly all present—and the thought that he is no more with us is certainly a very great grief to all who have known him, and a loss to science and to England. We look back upon Mr. Scudamore's presidency with great satisfaction, considering all that he did for the Society, and his loss is deeply felt. Three of the presidents since I had the honour to serve are also gone—Mr. Walker, Col. Champain, and, within the past year, Sir Charles Bright. The first Atlantic cable of 1857 gave me the happiness and privilege of the acquaintanceship with Sir Wm. Siemens. In the course of the work, Sir Charles Bright was my colleague. He was engineer to the company, and during the thirty-three days when we were out of sight of land in the ever-memorable "Agamemnon" expedition of 1858, Sir Charles Bright was with us, full of vigour and enthusiasm. To his vigour and earnestness and enthusiasm in a great measure was due the existence of that cable, the temporarily successful cable of 1858, and all the great consequences which followed from it, even although that cable itself had a very short life, having only three months of working time, and a still shorter time of really useful, practical work. Still, we must always feel deeply indebted to Sir Charles Bright as a pioneer in that great work, when other engineers would not look at it, and thought it was absolutely impracticable; and we must always look upon our late colleague, lost within the last year, as having done much indeed for the subject of the Society of Telegraph Engineers (applause).

The Society of Telegraph-Engineers has grown not only in membership, but in the extent of its province from the time of its foundation until now. It became the Society of Telegraph-Engineers and Electricians a few years ago, and now the more properly representative title of the Institution of Electrical Engineers has been adopted. The original name included only telegraphy, but that was not then the only application of electricity to engineering. There was electro-metallurgy. Electro-metallurgy and telegraphy were the two, and I think the only two, branches of practical science to which electricity had then been applied; but since that time we have a vast augmentation of the field. We have telephony; we have electric transmission of power. The Society of Telegraph Engineers will recollect Sir William Siemens's introduction to it of that great subject of the electric transmission of power on a scale of practical usefulness. I think we may safely feel that to the Society of Telegraph-Engineers in a large measure is due that practical development of electricity. We have now power electrically transmitted through factories to drive separate machines by separate motor dynamos. We have electric haulage and electric tramcars. We have the application of electricity to naval and military purposes; and last, not least, we have the application of electricity to electric lighting. With all these grand subjects of applied practical science for our province, I think the Institution of Electrical Engineers may feel that it has a great and noble dominion.

But we must not forget that the province of the electrical engineer necessarily touches upon that of the civil engineer. When fourteen years ago I gave my inaugural address, I endeavoured to impress upon engineers and architects that architects made a great mistake in not being engineers, in not qualifying themselves as engineers, and doing the work of engineers; that architects do not do their duty to their clients in not being engineers and understanding the engineering of their own works, and making engineering science, particularly the dynamics of engineering, an essential part of the training of an architect. It is not necessary to make any animadversion, I think, upon electrical engineers in this respect. Electrical engineers know well that they must before all be engineers (hear, hear). They must be engineers, and they must learn electricity.

To young persons who have a taste for electrical machines (and who that is young has not a taste for electrical machines, and sparks, and flashes, and aurora borealis artificially made, and the smell of ozone—sulphur and phosphorus we used to call it!—which is one of the pleasing reminiscences of one's youth in working with electrical machines?) a word of advice may be useful. Every young person who has a fancy for electricity thinks he would like to be an electrical engineer. They think electrical engineering is all ether and electricity. Now, I have continually to impress upon anxious fathers and mothers that their boys must condescend to learn something of gross ponderable matter, and that electrical engineering is not confined to ether and electricity, but mechanics also is an essential part of the subject. It is, I think, an important practical point this—that the electrical engineer, or the youth or aspirant to that honourable profession, ought to learn mathematics and dynamics after having obtained the elements of a good general education. He ought to learn mathematics and dynamics well. Then a good deal of chemistry and regular mechanical and civil engineering should all be learnt; and electricity learnt besides. It may be said juvenile life is too short. I do not think it is. I think if the other subjects are well learnt electricity may be learnt in a few months. I am perfectly sure that if the youth is qualified in other departments, the mere addition of electricity to the education of a competent engineer will not take so very long a time as might be imagined (hear, hear), and that the merely educational part of the work will not be protracted unduly by adding electricity to the branches learnt in general engineering. I do not mean to say that if electrical engineering is the branch adopted there is not an endless and prodigious field of electricity proper in which the worker will learn every day of his life, though he lives for more years than any person present. I wished just to make these few remarks in the beginning, because they do seem to me of some practical importance, and worthy, therefore, of being put in the front of the address I have to offer as first President of the Institution of Electrical Engineers.

Now these remarks have suggested to me a subject for such a scientific exposition as I could possibly attempt to give in this opening address—ether, electricity, and ponderable matter. The demand for something like a mechanical explanation of electrical phenomena is not new, but it is growing in intensity every year. The proceedings of recent meetings of the British Association—and especially of the last meeting of the British Association—illustrate the growing desire to know something below the surface; to know something of the internal relations connected with the wonderful manifestations of force and energy which are put before us in the action of the magnet, in the working even of a common electrical machine and in electromagnetic phenomena. The addresses of Past Presidents of the parent Societies of Telegraph-Engineers and Telegraph-Engineers and Electricians illustrate also the growing desire to know something of the molecular theory or the dynamical theory of electricity and magnetism. Mr. Preece, in his address of 1880, pointed out how Maxwell had shown the velocity of light to be related to electricity in such a way that we can scarcely doubt but that the propagation of electromagnetic disturbance through space, which we have every reason believe does exist—which, in fact, from known laws we may say certainly does exist—is effected with a velocity equal to that of light, and that the propagation of electrical disturbance and of light may perhaps be identical. In support of these remarks, Mr. Preece alluded to the disturbances at the sun's surface and the simultaneous magnetic disturbances which had been observed in the telegraphs and in other operations of an electro-magnetic character on the surface of the earth.

In 1883 Mr. Willoughby Smith described shortly some experiments which I consider to be very beautiful and very instructive with which he was then engaged. Those experiments demonstrated and illustrated the screening effect of sheets of different kinds of metal upon electro-magnetic and electro-static inductions. Electric induction, simply, we may say, because we begin to fail to distinguish between electro-static

Digitized by Google

induction and electro-magnectic induction. In Willoughby Smith's subsequent work he gave an exceedingly beautiful set of experimental investigations of the screening effect of lead, copper, and iron, of which, as I have said, a slight sketch was given in his Presidential Address. A little earlier the subject was mathemetically worked out with great power by several mathematicians, but perhaps most notably by Horace Lamb. I feel it almost invidious to mention names when there are so many thorough workers who touched upon the same subject very closely. Charles Niven,* almost simultaneously with Lamb,† went through very much the same kind of work—in fact, obtained the same solutions of some important and interesting problems regarding electric currents in spherical conductors. I specially mention Lamb's name because the subject of screening is more particularly developed in his mathematical Paper.

In the memorable Presidential Address of Prof. Hughes, another allied branch of electro-magnetic induction was very admirably illustrated by experiments which are now more or less familiar to us all (hear, hear), but which have been of an immensely suggestive and stimulating character, both to mathematicians and to experimental workers. The very criticisms by mathematicians upon some of the experiments and modes of statement by Prof. Hughes have, with Prof. Hughes' own experiments, given a very large body of electric knowledge and electro-magnetic knowledge, which, without such stimulus and such mathematical and experimental scrutiny as it has led to, might have been wanting for many a year (hear, hear).

One of the earliest problems in which electric induction had to be considered was that of the submarine telegraph. The subject of induction in telegraph wires presented itself in a peculiarly perplexing way to the first workers in that department. There was the general knowledge of electro-magnetic induction between two wires, which had been worked out by Henry and Faraday in a very full manner. That was the only kind of induction which was thought of by some of the pioneers of submarine telegraphy. Another kind of induction was more thought of by others. That was the electrostatic induction due to the Leyden-jar charge of the insulated wire. Faraday, in this department, as in the other department, was the origin of nearly all that we now know. He explained in a very beautiful and clear way the electrostatic charge of the submarine cable, and showed how the electricity conducted through the cable from one end, to give what of potential is necessary in the middle or the other end of the cable—in the middle of the cable for any mode of working, at the other end of the cable for modes of working in which the other end is insulated—gave rise to the Leyden-jar charge. He pointed out (without going into any of these details, however), the doctrine of the conduction of electricity through the wire to supply the Leyden jar charge, which the wire must have, in the course of working, in order to be raised to the difference of potential from the earth required to cause the signal current to pass through it. Cromwell Varley made very important advances in that direction. At the meeting of the British Association in 1854 at Liverpool, he brought forward some important developments of Faraday's doctrine. And then came on the great Atlantic Cable question. I always remember how that question came upon me. I see in Prof. Stokes's presence with us this evening a reminder of the circumstances. I was hurriedly leaving the meeting of the British Association when a son of Sir William Hamilton, of Dublin, was introduced to me with an electrical question. I was obliged to run away to get to a steamer, by which I was bound to leave for Glasgow, and I introduced him to Prof. Stokes (applause), who took up the subject with a power which is inevitable when a scientific question is submitted to him. He wrote to me on the subject soon after that time, and some correspondence between us passed, the result of which was that a little mathematical theory was worked out, which constituted, in fact, the basis of the theory of the working of the submarine cable. In that theory electro-magnetic induction was not taken into account at all. The leaving it out of account was justified by the speed of signalling, which the circumstances of a cable exceeding 200 or 300 miles in length dictated. For a cable more than 200 or 300 miles long the speed of working was essentially limited by these electrostatic considerations—limited so much that the electro-magnetic induction certainly could have no sensible effect. But the possible speed of working in a cable of 20 miles or 50 miles, or even 100 miles, was so great that in short lengths like that, the electro-magnetic induction might well come into play. I worked out the subject partially myself. I found it necessary to do so to satisfy myself that the doctrine upon which the Atlantic cable project, then growing up, was ultimately founded, was thoroughly trustworthy. I found it necessary to investigate the question of electro-magnetic induction. This question was further forced upon me by communications that I had with my friends, Lewis Gordon, and the two brothers, Charles Wm. Siemens and Werner Siemens, with reference to Mediterranean cables. It was imagined that electro-magnetic induction alone was operative—that embarrassment in working through the submarine cable was due to electro-magnetic induction alone. On its being demonstrated that electro-magnetic induction could have no sensible effect on the signalling through proposed Mediterranean cables, the proposal to have two thin wires close together in order to obviate electro-magnetic induction was given up. Experiments in Germany had shown considerable electro-magnetic induction on short lengths of cable, and it had been supposed that there would be embarassment from this cause in the working of the cables, which would be diminished by using wires very close together. But this diminution of the electro-magnetic inductive influence would produce a corresponding increase in the electrostatic inductive influence; and when it was pointed out that the electro-magnetic inductive influence would be absolutely imperceptible at the highest speeds of working of the proposed cables, and that it would be the electrostatic induction which would limit the speed, the idea of making them of thin twin wires—two pairs of wires close together in metallic circuit—was given up, and the present type of submarine cables was adopted. But now it is very interesting to us to find that old question revived. I had myself laid it aside in some corner of my mind and in some slight corners of my note books for forty years. Within the last forty days I have really worked it out to the uttermost merely for my own satisfaction. But in the meantime it had been worked out in a very complete manner by Mr. Oliver Heaviside (applause), and Mr. Heaviside has pointed out and accentuated this result of his mathematical theory—that electro-magnetic induction is a positive benefit, it helps to carry the current. It is the same kind of benefit that mass is to a body shoved along against a viscous resistance. Suppose, for instance, you had a railway carriage travelling through a viscous fluid. Take a boat on wheels so that the more massive body will not sink deeper in the fluid than the less massive body. Take a boat on wheels in a viscous fluid. We will shove off two boats with a certain velocity—the boats of the same shape; but let one of them be loaded to ten times the mass of the other—it will take greater force to give it its impulse, but it will go further. That is Mr. Oliver Heaviside's doctrine about electro-magnetic induction. It requires more electric force to produce a certain amount of current, but the current goes further. It is a very crude way in which I am putting it. I am not doing justice, of course, I know, to his statement in one short sentence. The whole question is treated in the most complete mathematical way. The effect of electro-magnetic induction and electro-static induction taken together (and they cannot be separated) is fully worked out. One thing that was known of old is made a point of in Mr. Heaviside's treatment of the cable problem; that is, the beneficial effect of leakage in respect to clearness of signals. Old telegraphists remember that. They always used to say three or four good leaks in a cable, if they would but kindly remain constant, and not introduce extra trouble by earth currents, would make the signalling more distinct. That used to be well known, and the reason used to be fairly well known; mathematical theory had pointed it out. Now Mr. Oliver Heaviside has taken up

* "On the Induction of Electric Currents in Infinite Plates and Spherical Shells," *Phil. Trans.* Roy. Soc., 1881, p. 307 (read Jan. 29th, 1880.)

† "On Electrical Motions in a Spherical Conductor," *Phil. Trans.*, Roy. Soc., 1883, p. 519 (read April 5th, 1883.)

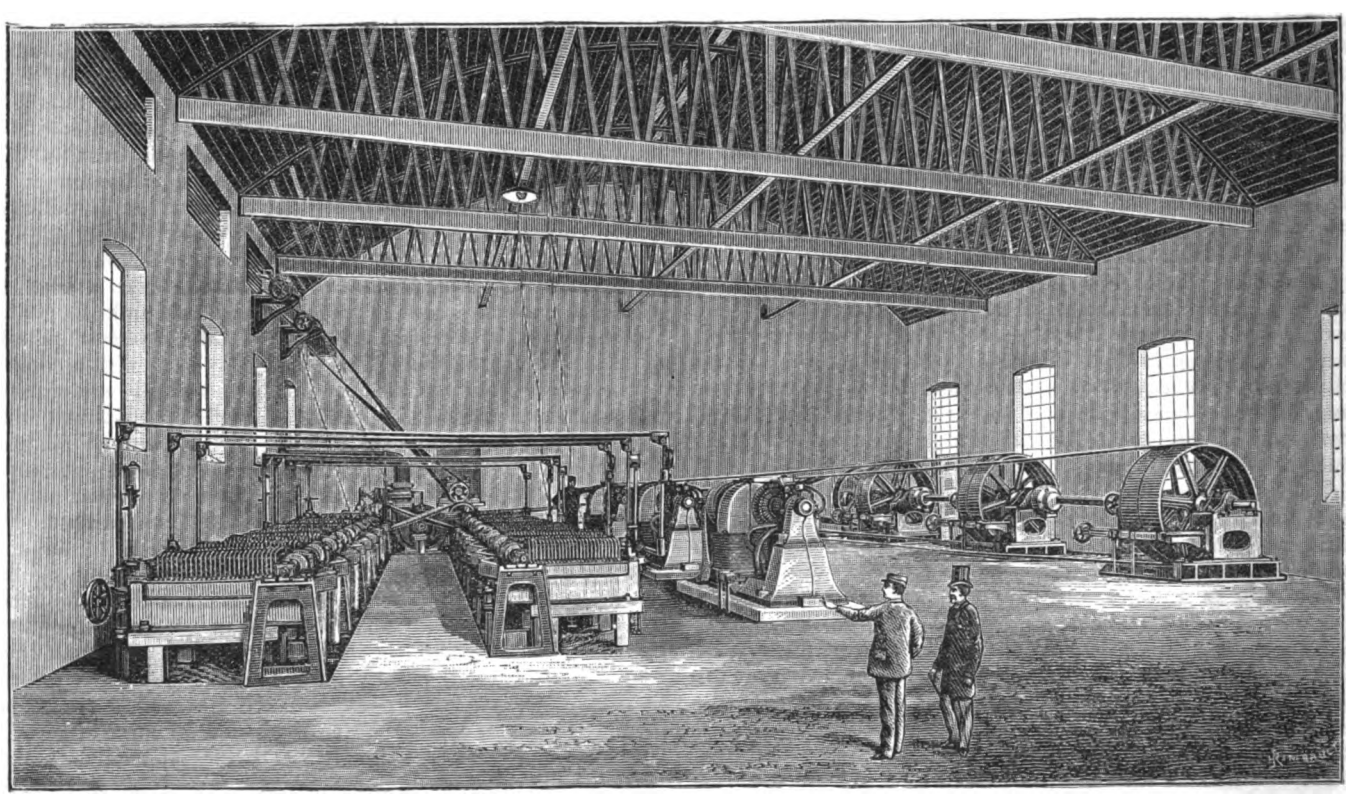
Digitized by Google

that subject again and included it in his work. He has included it along with electro-magnetic induction, and this point he has particularly accentuated. It is a practical point of imimportance that the question of clearness of signals is not simply or even very importantly this—how much is the current attenuated at the remote end of the cable? how much is the amplitude of the electric current in one mode of working, or of the variation of electric potential in another mode of working, altered in transmission through a thousand miles or two thousand miles of cable? A certain range is given at the sending end; and what is the range at the receiving end? That is an important question, but it is not the most important question with reference to clearness of signalling; in fact, we might almost say it is not an important question at all. It is not the smallness of the signals at the receiving end that is the real difficulty in a submarine cable just now at all; it is the running of one signal into another; it is the want of correspondingly definite distinctions of single signals or of a group of signals at the receiving end and at the sending end.

Now, in the mathematical theory there are two things to be considered in respect to the distortion (as Heaviside called it) of the signals in passing through the cable. One thing to be considered is the retardation of phase; another is the diminution of amplitude. If the retardation of phase was the same for alternating currents of all periods, then this retardation of the phase would be of no consequence whatever—it could not diminish the distinctness at all. Again, if the diminution of the amplitude was precisely in the same proportion for alternating currents of all periods, then when we come to make non-periodic signals we should find that the signals would be transmitted with perfect sharpness. In fact, if we compare the transmission of electric signals through a wire with the transmission of sound through air, we have in the course of transmission of sound through air great attenuation by distance, inversely as the square of the distance in fact, but the same for all notes; and again retardation of phase depending upon the velocity of the sound, the same for all notes. The result is that speaking, and musical performances, and signals of all kinds in air lose none of their clearness by distance. It is just a question whether at the very greatest distance at which a sound can be heard there is any want of clearness due to different attenuations of the different notes or of the different elements forming the compound sound, or to difference of retardations of phase. I must not occupy you too long with this subject, but it is one of large practical importance. Heaviside points out that electro-magnetic induction causes a less great difference in the attenuation of different periods than there is without it; and that electro-magnetic induction (as we knew forty years ago) tends to reduce the retardation of phase to the same for all different notes—that is, to the retardation equal to what would depend on a velocity not very different from the velocity of light if the signals have but sufficient frequency. That velocity was then and is still known as the velocity which is the conductance in electrostatic measure, and the resistance in electro-magnetic measure of one and the same conductor. But its relationship to the velocity of light was brought out in a manner by Maxwell to make it really a part of theory which it never was before. Maxwell pointed out its application to the possible or probable explanation of electric effects by the influence of a medium, and showed that that medium—the medium whose motions constitute light—must be ether. Maxwell's "electro-magnetic theory of light" marks a stage of enormous importance in electro-magnetic doctrine, and I cannot doubt but that in electro-magnetic practice we shall derive great benefit from a pursuing of the theoretical ideas suggested by such considerations. In fact, Heaviside's way of looking at the submarine cable problem is just one instance of how the highest mathematical power of working and of judging as to physical applications helps on the doctrine, and directs it into a practical channel.

(To be continued.)

THE HERMITE ELECTRO-CHEMICAL BLEACHING PROCESS.



THE HERMITE ELECTRIC BLEACHING APPARATUS.

The accompanying illustration represents the arrangement of the plant for the Hermite electrical bleaching process, lately installed at Messrs. Evans and Owen's Paper Works, near Cardiff. The plant is capable of producing equal bleaching effect to two tons of bleaching powder per twenty-four hours, and was constructed and installed by Messrs. Paterson and Cooper to the order of the Hermite British Electro-Bleaching Company. Briefly described, the Hermite process consists in manufacturing a solution of high bleaching

Digitized by Google

power by electrolysing an aqueous solution of magnesium chloride. The salt is decomposed by the current at the same time as the water. The nascent chlorine, liberated from the magnesium chloride, and the nascent oxygen, liberated from the water, unite at the positive pole, and produce an unstable oxygen compound of chlorine of very high bleaching power. The hydrogen and the magnesium go to the negative pole; this last decomposes the water and forms magnesium oxide, whilst the hydrogen is disengaged. If in this liquid coloured vegetable fibre is introduced the oxygen compound acts on the colouring matter, oxydising it. Chlorine combines with the hydrogen to form hydrochloric acid, which, finding itself in the presence of magnesium in the liquid, combines with it and forms the initial chloride of magnesium. Thus a complete cycle of changes goes on so long as the electric current acts on the solution in the presence of colouring matter. The cycle is a perfect one, in which there are four elements—the electric current, chloride of magnesium, water, and the colouring matter. Only two of these elements are used up whilst bleaching—the electric current and the water. The magnesium chloride serves over and over again. There is only a simple displacement of molecules, and the chlorine acts as a vehicle to discharge the nascent oxygen on the colouring matter. Mr. Hermite, after prolonged research, has arrived at the conclusion that it is magnesium chloride which of all chlorides gives the only commercial and complete results.

The plant at Messrs. Evans and Owen's works consists of 20 "electrolysers" arranged in two rows, through which the solution of magnesium chloride is constantly circulated. Each electrolyser consists of a galvanised iron box open at the top and with a perforated pipe at the bottom. The box is filled with the electrodes, which consist of a series of platinum plates connected to the positive pole of the dynamo, and a series of circular zinc plates interspaced with the platinums and connected to the negative pole of the dynamo. The solution is admitted at the bottom through the perforated pipe, and overflows the sides of the box, passing in between the plates, and being decomposed, then falls into a cement tank underneath. From this bottom tank it is taken by means of a 12in. centrifugal pump into the tank above, and is ready to pass through the electrolyser again according to the strength required. The top tank is a large, egg-ended boiler, and is connected to each electrolyser by means of a rubber pipe and cock.

It is from the top tank that the solution is pumped over to the bleaching mill, a distance of some 50 yards, by means of an 8-inch centrifugal pump, where it is received in tanks, from which it is drawn as required. The method of working is very simple; the pulp ready to be bleached being in a "potcher," the electrolyser bleaching solution is run in, and the washing drum kept working; as the solution passes through the pulp its bleaching power is exhausted, and it is returned by means of a pipe to the top tank from which it originally started, and from whence it again passes through the electrolyser and is regenerated.

The amount of solution remaining in the pulp after bleaching is recovered by a system of displacement in drainers or by means of a press plate.

The current is supplied by three of Paterson and Cooper's Phœnix shunt-wound dynamos, each giving a current of 1,000 to 1,200 amperes, with a difference of potential at the terminals of 40 volts. The electrolysers are arranged in series, eight on each of two dynamos and four on the other, this has been so arranged that another four may be added when required. Each circuit has an ammeter and voltmeter connected. The dynamos are driven by a compound condensing engine of the tandem type, capable of indicating 300 horse-power, the amount actually taken up at present being 200 horse-power.

An important part of the plant is that for the preparation of the magnesia necessary for keeping the solution basic. It consists of a vertical tank fitted with a stirrer, in which lime milk is made. This is run from thence into a shoot, discharging into any one of three vertical tanks, each fitted with a stirrer. These tanks are all placed above the main tank supplying the electrolysers, so that by merely opening a cock the "base," when prepared, can be run down at will. The three vertical tanks are partly filled with a solution of magnesium chloride, and then filled to the top with the lime milk. The lime throws down the magnesia, the calcium chloride which remains is siphoned off, the magnesia being then washed twice is ready for use.

The cost of bleaching by this system compares very favourably with the old process.

The fibres bleached are not deteriorated in strength to anything like the same extent as with bleaching powder.

There are many modifications of the process for the bleaching of linen and cotton yarns, piece goods, &c., and also many different forms of apparatus, which are the subject of numerous patents in the names of Messrs. Hermite, Paterson and Cooper, in England and abroad.

The plant has been manufactured and erected by Messrs. Paterson and Cooper, under the personal superintendence of Mr. Hermite.

This process has been adopted on a large scale by several important paper makers, some of whom, after prolonged trial upon a limited scale, have given extensive orders.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714.

All Communications to be addressed to "The Electrician," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician."

All letters intended for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.

"The Electrician" is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.

SPECIAL NOTICE.

Owing to the increase in the number of pages of "The Electrician," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
„ Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"The Electrician" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Trade Advertisements *intended for the current issue must be handed in not later than First Post on Thursday morning.*

Small Prepaid Advertisements *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"The Electrician" Printing and Publishing Company (Limited) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "The Electrician" Electrical Trades' Directory and Handbook. *The Directory was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 will SHORTLY BE READY.

CONTENTS OF THE CURRENT NUMBER.

SPECIAL NOTICE.

With the next number of "The Electrician" will be published a Steel Plate Portrait of Sir William Thomson, F.R.S., President of the Institution of Electrical Engineers.

"Electrician" Subscribers should receive this Plate Gratis. To non-subscribers the price of "The Electrician" for January 25th will be Sixpence.

Subscribers should promptly address complaints of non-receipt of the Portrait to The Publisher.

"ETHER, ELECTRICITY AND PONDERABLE MATTER."

Nothing is perhaps more remarkable in Sir William Thomson's career than the fact that whilst his attention has been so unremittingly bestowed upon those questions which are amongst the most difficult of any in the whole range of physical and mathematical science, yet he has nevertheless continued to maintain the closest touch with the practical everyday side of life; so that, for instance, his inventions are marked no less by minute and painstaking attention to detail than by the brilliancy and originality of their conception. It was in this spirit that on Thursday evening, before addressing himself to the subject proper of his discourse, he took occasion to insist upon the elementary fact that "electrical engineering is not confined to ether and electricity," but that the would-be electrician "must condescend to ponderable matter"—in other words, that first and foremost he must be a mechanical engineer, and something he must also know (if possible, a good deal) of mathematics, dynamics and chemistry. Doubtless this is a warning which cannot be too often repeated by the leaders of the profession, and it is especially valuable when thus delivered *ex cathedra*.

Digitized by Google

But we venture, after all, to think that one of the most valuable lessons which the members of the Institution of Electrical Engineers will have derived from this Address may be summarised in the terms of a proposition almost the converse of the above. Electrical engineering, we have been forcibly reminded, is not confined to electricity and ponderable matter. There is also a mysterious something without which (however we may be content to ignore it in our everyday work) no single step can be taken towards the least understanding of the intimate nature of the processes with which the electrician is concerned. It is undoubtedly, on the one hand, a legitimate subject for gratification that the theory of applied electricity can be made to rest upon a practical basis in which we virtually neglect the ether, and think of electricity and of ponderable matter alone; but, on the other hand, it is surely a healthy and a desirable thing that our thoughts should now and again be directed towards that occult and mysterious medium of whose properties we may know a little, but whose mechanism and structure the acutest intellects fail as yet even to surmise, save incompletely. Scarcely need we stay to add that it is to Sir WILLIAM THOMSON himself that we owe the most far-reaching and the most successful attempts that have hitherto been made to grapple with the profound difficulties here presented. For forty-two years, as he told us, the attempt to solve these questions has been with him day and night, "not all of every day, nor all of every night, but there have been very few days and nights in which I have not been trying to find it; but I have not succeeded in finding it yet."

The beautiful gyrostatic experiments which were exhibited at the close of the Address will have done much to assist the non-mathematician to conceive the actual possibility of a mechanical explanation of magnetic phenomena. Combining the gyrostat with the "molecular skeleton" framework of constant area we are provided with something approaching a concrete illustration of a medium which is competent to perform very many, though not all, the operations required by electromagnetics. Yet electrostatic phenomena are still, as Sir WILLIAM expressed it, left out in the cold, and their inclusion is even at present unimaginable. It is his abiding conviction that in the ether "there must be some kind of structure . . its molecules must have some shape; they must have some kind of relation to one another," and undaunted by apparently irreconcilable demands, he still looks forward confidently to the ultimate and complete solution of the problem. We may be permitted to quote the concluding passage of the Address:—

"And there, then, I am afraid I must end by saying that the difficulties are so great in the way of forming anything like a comprehensive theory that we cannot even imagine a finger-post pointing to a way that can lead us towards the explanation. That is not putting it too strongly. I only say we cannot imagine it. But this time next year; this time ten years; this time 100 years, probably, it will be just as easy, perhaps, as we think it is to understand that glass of water, which seems now so plain and simple. I cannot doubt that these things, which seem to us so mysterious, will be no mysteries at all; that the scales will fall from our eyes; that we shall learn to look on things in a different way; when that which is now a difficulty will be the only common-sense and intelligible way of looking at the subject."

Now, it is scarcely necessary on our part to disclaim the intention of offering any criticism whatever upon Sir WILLIAM THOMSON'S views, as embodied in this memorable Address; still less shall we venture to assign any probable limit to the future extension of human knowledge. There is, nevertheless, one simple question which we may perhaps usefully raise, especially in the light of certain quite novel conclusions, to which we shall draw attention. So far as we have been able to gather from the whole of Sir WILLIAM'S treatment of the subject, he looks upon the ether as consisting, in some sense of the word, of matter. But we are not clear to what extent he regards the ether as being subject to the same dynamical laws as those which have been derived from our experience of ordinary matter. It must be remembered that these laws are based on experience, and we are unable to say that as we know them so they must inevitably have been. How, then, can we feel sure that they at all hold good for a medium upon which the law of gravitation asserts no claim? If, for instance, the ether be not matter at all, would the laws of motion as we know them necessarily hold good for it, or would it still be possible to hope for an intelligible exposition of the phenomena it presents? Many years ago Sir WILLIAM sought to obtain at least an inferior limit to the density of the ether in planetary space.* His method is based upon the measurements by POUILLET and HERSCHEL of the whole amount of solar radiation received upon a given surface in a given time, and upon an assumption with regard to the distortion of the ether in any wave which is considered to be small compared with the length of the wave. In the result he showed that the mass of the ether contained in a cubic mile of space near the earth must be *at least* $\frac{1}{1,000,000,000}$lb. And to show that this is not by any means a surprisingly small quantity, he calculated that at the distance of a few radii from the surface of the earth a cubic mile of air (if the atmosphere extends so far, which is for other reasons improbable) would be represented by a fraction of a pound, having 329 figures in the denominator! Remembering that this calculation assigned only the *inferior* limit of the density of the ether, it is instructive to compare the result with some figures recently obtained by M. HIRN, and which will be published in a forthcoming work of considerable importance, entitled "Constitution de l'Espace Céleste." M. HIRN attacks the problem by calculating, in the first instance, the density of a medium whose resistance would be capable of producing a secular acceleration of half-a-second per annum in the mean motion of the moon. He finds that this demands the presence of one kilogramme of matter disseminated in a space of 975,000 cubic kilometres, equal to one pound in 104,000 cubic miles; so that under this supposition the medium would have a density considerably greater than that assigned by Sir WILLIAM THOMSON for the inferior limit of the actual ether. In fact, M. HIRN'S medium has a density equal to about one millionth of the vacuum of a Crookes tube.

But what are the consequences of the presence of even so attenuated a medium when diffused in space through which a planet tears its way? Assuming a very high specific heat, he finds that, at the surface of the moon the ether would be raised by the shock of the collision to a temperature of no less than 38,000°C.! Moreover, in a passage which we do not quite follow, M. HIRN, if we understand him right, says that the surface of the moon itself would attain to a temperature of about 300,000° C. This calculation refers, of course, to the case of a planet which possesses no atmosphere, but the consequences would be equally serious for the Earth, since the atmosphere would soon be driven off altogether by the combined heating and shearing effects. If these calculations be capable of verification, and even when allowance is made for the greater density of the medium assumed by M. HIRN, it seems to us that the difficulty of imagining the ether to be in any intelligible sense a modification of ordinary matter is greatly intensified.†

* "Mathematical and Physical Papers," Vol. II., p. 30.

† It is necessary, however, to remark that both Adams and La Place came to the conclusion that ether resistance if present would have no sensible effect upon the mean movement of the nodes or of the lunar perigee.

Digitized by Google

Dr. YOUNG* long ago wrote that "the luminiferous ether, pervading all space and penetrating almost all substances, is not only highly elastic, but absolutely solid!!!" And the learned doctor's trebly pointed exclamation does not too much emphasise the incredible character of the statement. HERSCHEL† calculated the force which may be supposed, according to the undulatory theory of light, to be constantly exerted at each point in space, and finds it to be 1,148,000,000,000 times "the elastic force of ordinary matter at the earth's surface"; so that the pressure of ether per square inch (under, or rather within, which we live and move and have our being) must be about seventeen billions of pounds. But as Sir WILLIAM THOMSON pointed out in the Baltimore lectures, these difficulties tend to diminish in face of the fact that properties at first sight almost equally paradoxical may be observed in ordinary matter. The supposition that the ether acts like a perfectly elastic solid for vibrations executed in periods of from the 100 to the 1,600 billionth of a second, and is yet highly mobile to bodies having a velocity of, say, 20 miles a second, is less difficult of comprehension in view of the fact that a tuning fork may be made of Burgundy pitch—a substance which, therefore, behaves as an elastic solid for vibrations with periods of a small fraction of a second. Yet a bullet will by its own weight penetrate into it several inches in the course of a few months.

The bewildered student will be inclined to say, "for this relief much thanks;" but even now it is refreshing to recollect that we have still Ohm's law and the Parallelogram of Forces, and that the advantage (in certain cases) of a closed magnetic circuit remains wholly unimpaired.

THE ELECTRIC LIGHTING CONCESSIONS IN PARIS.

The following is a list of the streets marking the boundaries of the districts in which concessions have been granted by the Paris Conseil Municipal to electric lighting companies:—

Gaston Cenisier District.—Avenue de la Grande-Armée, Avenue des Champs-Elysées, Rues de Rivoli, du Louvre, Montmartre, du Faubourg-Montmartre, de Châteaudun, de Londres, de Constantinople, de Rome, Cardinet and de Tocqueville.

The Société Anonyme du Secteur de la Place Clichy District.—Boulevard Pereire, Rue de Rome, Boulevard Haussmann, Rues du Havre and d'Amsterdam, and the Avenus de Clichy and Saint-Ouen, up to the fortifications.

Victor Popp Company's District.—Rue de Belleville, Faubourg du Temple, Place de la République, the Grands Boulevards, Rues Royale and de Rivoli, Place de la Concorde, and the Quais on the right bank up to the fortifications.

The Surrey-Montant Company's District.—Boulevards Ornano and Barbès, Faubourg Poissonnière, Rues Poissonnière, des Petits-Carreaux, Montorgueil, Baltard and du Pont-Neuf, Quais des Orfèvres and du Pont-Neuf, Rue de la Cité, Parvis Notre-Dame, Pont d'Arcole, Rue du Temple, Place de la République, Faubourg du Temple, Rue de l'Entrepôt, de Lancry, des Récollets, Faubourg Saint-Martin and Rue de Flandre.

The Edison Continental Company's District.—Avenues de Saint-Ouen and de Clichy, Rues de Clichy and de la Chaussée-d'Antin, the Grands Boulevards up to the Rue Richelieu, the Place de la Bourse, the Rues Joquelet, Montmartre, Grands Boulevards up to the Rue du Faubourg-Saint-Denis, the beginning of the Rue du Faubourg-Saint-Denis, the Faubourg Poissonnière up to the Rue d'Enghien, the Rue Bergère, the Rue du Faubourg-Montmartre, Rue Grange-Batelière, Rue Geoffroy-Marie, Rue Richer, Cité Trévise, Rue Bleue, Rue Lafayette, Place Cadet, Rue Rochechouart, Rues Clignancourt, Ordener and du Mont-Cenis.

The Marcel-Deprez Company's District.—The Boulevards Ornano and Barbés, the Boulevard de Magenta, Place de Roubaix, Rue de Dunkerque, the Boulevard Denain, Rue du Faubourg-Saint-Denis, Rue d'Aboukir, Rue du Caire, the Boulevard de Sébastopol, the Boulevard Saint-Martin, Place de la République, Rue de la Douane, the Quai de Valmy, and the Rue d'Allemagne.

When the question of these concessions first came before it, the Conseil Municipal decided that the districts conceded to the companies should form a series of segments, proceeding from the centre of Paris to the fortifications, and stipulated that within four years the *concessionnaires* should be ready to provide light in any and every part of their district. This naturally gave rise to strenuous opposition on the part of the companies. After prolonged consideration of the matter, concessions were finally granted under a security of 300,000fr. in each case, except that of the Clichy Company, whose district is smaller, and which only has to deposit 100,000fr., and upon the condition that cables are laid in all the large streets within two years, and within four years in every street where ten lamps are asked for per every ten metres. These districts, it may be remarked, overlap in several parts, and the companies can, therefore, compete in these "quartiers." The concessions also only refer to private lighting, the companies merely holding the right of laying mains in certain streets, with a view of furnishing the householders with the current. As to public lighting, that will become the object of conventions between the companies and the authorities. It is expected that work will now be actively pushed forward by the various *concessionnaires* in the districts allotted to them.

The municipal central station at the Halles Centrales still forms the subject of lengthy discussions. The last question which has arisen is that of the nationality of the dynamos. Since the days when it issued the famous *cahier des charges* relating to the distribution of electricity, the Conseil Municipal has posed as the protector of French industry. Quite recently, after having voted the concessions mentioned above, the Conseil, in order that there might be no fear of misunderstanding, passed a resolution to the effect that in Article 27 of the *cahier des charges* the word "apparatus" included wires and lamps as well as engines and dynamos, all of which will now have to be of French manufacture in the case of the *concessionnaires*. This being so, great astonishment was caused by the Conseil Municipal accepting the tender of M. Patin, agent in France for M. Ferranti, of London, since it appeared that the Conseil had no intention of imposing upon itself, in the case of the station at the Halles Centrales, the stringent conditions it sought to impose on the *concessionnaires*. On December 31st MM. Dumay and Paulard called attention to this anomaly, and the committee which had been charged with awarding the contracts immediately protested and gave as an excuse the superiority of the Ferranti machines. The only two electricians on the committee were M. Mascart and M. Potier. M. Mascart's opinion was as follows:—"If I had to start a central station myself I should give my preference to the Ferranti machine. But as a representative of the city of Paris, and looking at the matter from this point of view, I hold that the superiority of the Ferranti machine is not so great as to oblige the city of Paris to have recourse to foreign industry." M. Potier explained himself at considerable length. The choice, he said, lay between the Edison and Ferranti tenders; the latter was 40,000fr. dearer, but yielded 12 per cent. more. Each Zipernowski machine would give 68,400 watts at the terminals, each Ferranti 75,600 watts. M. Patin's machines, it is true, were 113,000 watt dynamos, and the engines arranged for were only equal to 90,000 watts, but M. Patin gave a guarantee in writing that his machines would have an 88 per cent. efficiency, even if provided with only 140 horse-power engines. Such being the case M. Potier said that he considered the Ferranti tender the best. The Conseil finally decided as follows:—"All the material for the municipal central station will be purchased exclusively from French firms, the efficiency being the same. The Conseil Municipal will be the judge, after a report from a technical committee nominated by the Conseil."

It will thus be seen that the affair remains in a somewhat confused and uncertain condition.

NOTES ON THE DESIGN OF ELECTRIC MOTORS.*

BY ALBION T. SNELL.

In discussing the design of electric motors it will be necessary to first of all consider the relation between the dynamo and the motor. The dynamo may be defined as a machine which converts mechanical work into electrical energy. The motor, when supplied with electrical energy, gives out mechanical work. So far, one is the converse of the other, and the dynamo is said to be a *reversible* machine.

The extent to which this is true depends very largely on the size of the machine under consideration. This follows from the fact that no matter how bad the design of motor, how weak the field, or how small the magnets or armature, it is sure to *run*. But a badly designed dynamo—one with relatively weak field-magnets say—will

* Young's *Works*, Vol. I., p. 415.

† Familiar Lectures on Scientific Subjects, p. 282.

* Paper read at the City and Guilds of London Institute Old Students' Association, on Wednesday, January 16th, 1889.

Digitized by Google

often not excite at all. Or again, the proportions of armature and field may be relatively correct, but the mass so little that the like result obtains. Why is this, if the dynamo be a reversible machine It has been shown that the reactions in the dynamo armature are not the same as those in the motor. And it is now generally admitted that the effect of self-induction in the dynamo armature is to increase the lead, while in the motor it tends to diminish it. And Mr. Mordey has pointed out that in the generator the effects of self-induction in the armature windings are opposite to those of the Foucault currents in the core ; but in the motor they tend to increase each other.

The writer has had these differences brought under his notice very forcibly in the course of his experience, having been connected directly or indirectly with the design of more than 400 machines, varying in output from ·1 horse-power to 100 horse-power, and from 20 watts to 70,000 watts.

The chief cause of this difference between dynamo and motor is to be found in the mutual effects of armature and field. Profs. Ayrton and Perry so far back as 1883 showed, both mathematically and practically, that in the motor the magnetism of the armature and that of the field *might* be added ; in fact, the motor-effort is proportional to the magnetic strength of both armature and field-magnets, while in the dynamo the field due to the armature, considered as an independent magnet, must necessarily subtract from that of the magnets. These main distinctions occur in the nature of things. Their magnitude at first seems to be considerable ; but really the effect depends very largely on the actual dimensions and the relative proportions adopted.

An ideal dynamo has an armature with neither internal resistance nor magnetism *per se*. The field-magnets alone are the source of lines of force. This condition may be the more nearly attained as the size and weight of the machine be increased. All text-books tell us that the field-magnet should be as powerful as possible, and the armature relatively weak. The exponents of the "reversible theory" and its corollary, "the better the dynamo the better the motor," appear to have had more experience of large machines than small ones. And their *experimentum crucis* necessarily leads them to such views. When such authorities as Hopkinson and Silvanus Thompson, Kapp and Mordey, assert anything electrical, few venture to disagree. But I beg to submit that an extended experience with small and medium size machines would modify their views, especially if weight-efficiency be an object in the design.

Be this as it may, a motor weighing 70lb. can be made to give one B.H.P. with 70 per cent. efficiency of conversion ; but the same machine run as a dynamo would require nearly 50 per cent. more speed to give an output of 746 watts, and even then the efficiency between output and belt power would be nowhere near 70 per cent. If this be true, and I think it beyond dispute, the theory and corollary require some modification. The approximation to the same efficiency when used as a dynamo or motor becomes the more apparent as the size of the machine is increased ; but even up to 50 H.P. I prefer to make certain structural differences in the design of dynamos and motors, particularly if they be series-wound. With shunt-machines the difference seems to be less marked owing to the field being nearly constant. If I mistake not, both Hopkinson and Mordey have founded their opinions on observations made from large shunt-machines.

Much more might be said on this branch of the subject, and numerous actual experiments might be given in support of my views, but this would digress too much from the object of this Paper. With these introductory remarks on the character of motors and their relationship to dynamos, I will pass on to the general design of motors.

There are two broad lines on which motors can be designed. They depend entirely whether weight and overall dimensions enter into the problem. It is only necessary to admit that a powerful armature with many ampere-turns and a relatively weak field will give the same torque as a strong field and a weak armature. Granting this, we can design a motor to give a certain torque independently of the total weight to some very considerable extent. We shall be guided in the proportion of armature and field by the work expected of the motor, by the price allowed for production, by the intended cost of future maintenance, and by the desired life. These two methods of design depend on the point of starting. In the *first* we take an armature of given size, select a certain surface velocity, and build the field as small as possible to give the desired torque. In the *second*, a certain type of field iron being determined on, we select an armature of sufficient cross-section to give the required results. The first of these two methods is by far the more scientific, inasmuch as the dimensions of the most costly part of the motor can be made a minimum. The second method, however, will sometimes occur in practice, and it is well to note the possible results of this as well as those of the more general case.

When designing a motor to do particular work the following points should be considered :—

(1). What is likely to be the average torque on the motor and driven shaft ?

(2). Is the motor to run continuously or only for short periods at more or less frequent intervals ?

(3). What variations of load may be expected ? and

(4). What will be the maximum torque on the motor shaft ?

(1 and 4) will determine the characteristic of the motor and the particular part of the curve at which the average torque shall be arranged to fall.

(4) will determine the size of the shaft and strength of the bearings.

(1) gives us the ratio of the speeds between the motor and the driven shaft.

(2 and 3) determine the limiting safe rise of temperature,

While the winding must be designed to satisfy all the conditions as nearly as may be.

It is not possible within the limit of a short Paper to thoroughly analyse the different points to be observed. The general method can alone be indicated, and experience must teach the engineering student the rest. I will roughly run through the several conditions of design, and give such hints as appear likely to be of use.

The first thing to be noted is the torque on the driven shaft. This is not always an easy thing to get at owing to the want of a little scientific nous in the ordinary mechanic. If, however, this be known it is possible to determine within a few per cent. the required current, and the best ratio of gearing to get a maximum average efficiency from the motor. If this be accomplished the motor will be a success. If the motor be designed on the assumption of so much horse-power being required, and gearing be accordingly selected, it probably will happen that, though the estimate of power be fairly correct, the motor will be unsuited to the work. The current, and consequently the torque on the motor-shaft, will probably be excessive. The efficiency of the motor will thus be low, and the electrical horse-power absorbed too great, while, further, the speed will be too slow. The obvious remedy would be an increase in the ratio of the intermediate gearing. But if the surface velocity of the motor be correctly designed the increased speed will be too great, and, consequently, introduce other difficulties ; in fact, the motor will be a failure—not from any intrinsic fault, but simply because improperly designed for the work.

Daily one comes across machines driven by electricity, steam, air or water, in which the same fault appears. The speed of the prime shaft is not properly proportioned to that of the main or driven shaft. The consequent loss in possible efficiency is oftentimes not known, or if suspected, is ignored. This sort of thing did well enough years ago ; but addressing a body of educated men who are likely to occupy leading positions among the engineers of the immediate future, I cannot pass it by without protest. I therefore beg to impress on you the necessity of determining in some way or other the actual number of ft. lb. required to make one revolution of the main shaft. Your ingenuity will suggest many ways of doing this in most cases.

As an illustration of my point, I will mention the many attempts to run electric tramcars by direct gearing, *i.e.*, without a counter-shaft. Nearly every firm that has tried the tramcar problem has made the attempt. The last has been the Sprague motor line at Richmond, United States. That the method is unsatisfactory and can be much improved on there is no doubt, for Mr. Sprague has already (October 2nd), 1888, published drawings of a new tramcar involving two motors with *countershafts*.

Engineers using electric motors seem to forget that, although very efficient at or about a certain speed, they are most inefficient at low speeds (*vide* curves on next page).* Too much stress is laid on th property of a motor exerting maximum torque at starting. It is forgotton that the efficiency is *nil* under the condition of maximum torque, and that it increases very slowly until the point of 50 per cent. is reached. There are other sides, of course, to the question ; but I wish here to strongly emphasise the primary condition of motor design, viz., attention to the torque of motor and main shaft.

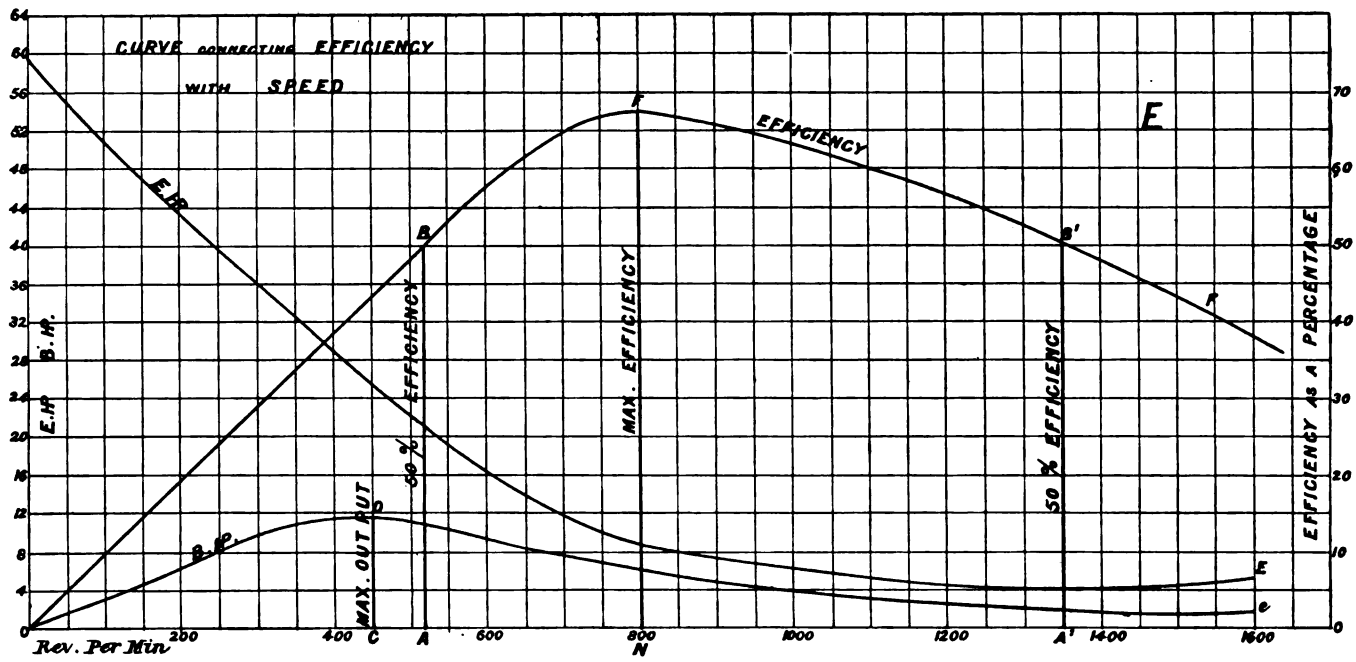
Having, then, determined the torques of the system the ratio of our gearing is known. Let us suppose that the motor torque be $\frac{1}{10}$th that of the main shaft, and that the gearing be accordingly in the ratio of 1 : 10. We have now to select an armature that will give us this torque at the speed required, satisfying also the conditions of durability, and that the rise of temperature will not exceed a certain limit, say 60° F., above the temperature of the room.

The mathematical expression for the torque of a motor is simple.

Let T be the torque. The output required of the motor at n revolutions per minute is, say, 1 B.H.P.

* Curve E E is the values of the E.H.P. for the different speeds, the motor running at constant potential. O c is an approximation to the corresponding B.H.P.; and O F F is the commercial efficiency (plotted to another scale). It will be noted that the efficiency increases at first with the speed, and, after attaining a maximum, slowly decreases, having passed through two points of 50 per cent. efficiency.

Digitized by Google



CONSTANT E.M.F. 400 VOLTS.

Then, $$T = \frac{B.H.P.}{2\pi n} = \frac{33{,}000}{2\pi n} = \frac{5{,}280}{n} \text{lb. ft. } (\alpha).$$

That is, the moment of the forces tending to turn the armature is equal to $\frac{5280}{n}$ lbs. acting at a radius of 1ft.

To get the exact pull on the periphery, it will be necessary to multiply this quantity by the ratio $\frac{1}{r}$, where r = the mean radius of the armature in feet.

The tangential strain on the wire is therefore

$$= \frac{5280}{n} \cdot \frac{1}{r} \text{lbs. } (\beta).$$

This latter quantity is what we require in designing the motor. In order to obtain the desired torque on our armature, we make $T = \frac{Z_a N t C_a}{2\pi}$ (γ), where Z_a = the number of lines of force passing through the armature, $N t$ = the number of turns of wire counted all round, and C_a = current flowing in the armature. It will be noted that the field does not come directly into the question. The function of the field-magnets is only to supply a magnetic field. It will be our care to so arrange the magnets and their windings that the proper value of Z_a is obtained. This is all that is necessary now. I shall have occasion to comment on this assumption later on when considering the field.

We have now to determine the values of Z_a, $N t$ and C_a.

C_a will usually be given us by the condition of supply and the horse-power required.

Z_a can be determined from the equation $Z_a = 2 a b z$ (δ), where z = desired number of lines per square inch, a = depth of core in inches, b = the length of armature *less the insulation* in inches.

Experience alone can tell us the best shape and size of armature core, but since the total cross-section $(=2 a b)$ is known no great difficulty presents itself. The depth of core will be mainly determined by the style of winding and the value of T. For a small torque a small armature and a large number of revolutions will be chosen; for a large torque a large, slow-speed armature is required. It will be necessary to note that a large cylinder or ring armature of short length is equivalent to a long drum of smaller diameter.

Then, assuming that the core be chosen, a and b are known. It only remains to substitute these values in (γ) and solve for $N t$. If the quantities are properly chosen $N t$ will have such a value that for a suitable current density the depth of winding will be about 10 per cent. of the core radius for cylinders and 15 per cent. for drums.

If the value of $N t$ be not a rational one the dimensions of the core must be altered. A few trials will illustrate this important part of the design, but practice alone can give ease and certainty.

In actual practice the matter is much simplified by previous experience and by fixed sizes of cores. It is then customary to select a wire to suit the current given, and to vary the speed so as to make the magnetic density suitable for the work. This is the crucial part of the whole thing. In other words, the motor is designed to give the required torque at a certain part of the characteristic. This point varies with the shape of the curve and with the conditions of work expected. My meaning will be more easily seen when the field-magnets have been discussed.

The best relative dimensions of armature and field cores is an open question. This is apparent from what has already been said. It depends entirely on the object aimed at. If weight efficiency be the desideratum, the armature *must* be relatively powerful, and the cross section of the cores may be made equal, allowing, of course, for the different permeabilities of the iron used. But if cheapness be the principal object, then a heavy field and a small armature are necessary. Speaking generally, the field strength has to be *relatively* greater as the size of the machine is increased.

The design of the motor field presents some considerable difficulty to the student. There are so many shapes and forms in vogue, and the same end seems to be attained with such opposite forms. With few exceptions, too, even old-established firms are continually changing their patterns, often with no apparent effect other than a weakening of the public confidence, and a considerable needless expense. Indeed, the engineering draughtsman seems to be at his wit's end to bring out a new design. Yet there is really no ambiguity on the subject. Text-books tell us the best form of magnet is that, *cæteris paribus*, which offers the least magnetic resistance, with a maximum cross-section and a minimum perimeter. Theory then points to a horseshoe magnet, of circular form and round cross-section. Difficulties of construction, however, render this ideal form too costly, and the matter has to be compromised. It is to this endeavour to balance the advantages of theoretical indication with the necessities of engineering that we owe the numerous types of fields.

The design of the field is, however, not so important with the motor as with the dynamo, and a little consideration will enable the student to determine suitable proportions.

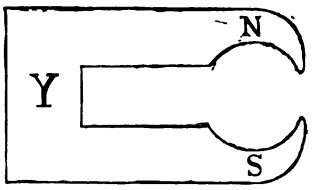
In the first place the field has to supply a certain number of lines of force to the armature, or is expected to form poles of such strength that, in conjunction with those found in the armature, the necessary torque will be obtained. If gross weight be neglected, and a minimum expenditure of copper be desired, the single horseshoe is chosen. Such machines are common enough, and may be made vertical, horizontal, or inverted. The two first types are the better, since the leakage is less. If a light-weight machine be required, even at the expense of copper, then double horseshoe magnets are used. This type involves twice the number of ampere turns to give the same strength of pole as the single magnet does; but yet it has considerable advantages. The resultant magnetic field is likely to be more uniform, and less trouble is given by the brushes as a rule. If the armature be of a large diameter—say more than 24in.—it is better to have a four-pole machine, although the ampere turns will be double that required with a double magnet, and four times that with a single one, if the same value of Z_a be taken. The Oerlikon dynamos, for the reduction of refractory ores, are made with six poles, and no doubt a more even distribution of magnetism is gained.

Having selected the form of magnet the question of length and cross-section of limb arises. Here the criterion is simply sufficient

Digitized by Google

space to wind the wire necessary to give the desired strength of poles and area enough to carry the magnetic flux required.

Here the student finds the first real difficulty. Let us review the position. We know the E.M.F. of supply or the allowed number of volts; the current is also approximately known from the B.H.P. and the assumed efficiency of conversion. The torque of the motor has been determined and expressed in terms of the magnetic flux through the armature iron, the effective cross-section, and the number of turns of wire; the dimensions and shape of the core are also agreed upon. So far it is a physical certainty. The problem now, primarily, is to design a field-magnet which, in conjunction with the armature, will give the required number of lines in the armature core. This is strictly all that is necessary. The question of economy of material and labour spent in the building of the field-magnets cannot be discussed here.



The magnetic flux in the magnets, to give a particular value of Z_a, I believe to be unattainable by direct calculation. Let Z_1 be the total lines induced at S in a single horseshoe magnet, and assume the lines to pass through the yoke Y and enter the armature at N. The leakage which occurs all along the windings, and on the neutral part or yoke, reduces the value of Z_1 to, say, Z_2. But Z_2 is still further lessened by leakage of lines from N to S outside of the iron or copper of the armature, and the effective number of lines is reduced to, say, Z_3. Now, the ratio of $Z_1 : Z_2 : Z_3$ will vary according to the shape of iron, the length of cores, the contour of the winding, and the average density of magnetism. The problem is already sufficiently complex, but yet this is not all. We have yet to take into account the useful number of lines induced in the armature by its own windings = say, Z_4. This quantity is usually ignored in text-books, but I know from a large number of experiments that, if we wish to be accurate in our treatment of the subject, this factor must not be neglected. I cannot go into figures, but the importance of the motor-armature, considered as an independent source of magnetism, may be understood from the following considerations:—

Take a large series machine designed as a dynamo, having a relatively powerful field and weak armature. Let this be run at such a speed and output that the top of the straight part of the characteristic is just reached. Observe the speed, current, and terminal E.M.F. Then drive it as a motor, using the same number of volts on the terminals, and load the brake till the same value of the current is attained. The speed will usually, I think, be found to be nearly as great as that required as a dynamo.

Next take a smaller machine, designed as a motor—*i.e.*, one with a relatively weak field, &c., and repeat the experiment. It will probably be found that for the same values of current and terminal E.M.F. the motor speed will be considerably *lower*.

This variation in the two speeds is due partly to the lead required in different machines when run as dynamos or motors, and also largely to the relative importance of the armature magnetism. Two simple equations will assist the study of the problem. Neglecting friction, let

E_d be the internal E.M.F. of the dynamo.

$E_m = \frac{\text{B.H.P.}\ 746}{C}$ be the internal E.M.F. of the motor.

E_T be the terminal E.M.F. both of dynamo and motor.

C R be the volts lost over the internal resistance of the machine.

L_d be the value of the reactions of the dynamo armature.

L_m be the value of the reactions of the motor armature.

It will be necessary to note that L_d and L_m will vary with the lead required.

For the dynamo we have—

$$E_d = E_T + (C R + L_d) \quad . \quad . \quad . \quad . \quad . \quad (I.)$$

For the motor we have—

$$\frac{\text{B.H.P.}\ 746}{C} = E_m = E_T - (C R + L_m) \quad . \quad . \quad . \quad . \quad (II.)$$

Now, the speed of the motor varies as E_m, and the speed of the dynamo varies as E_d. It follows, then, that the motor speed should be *less* than the dynamo by a quantity proportional to $(C R + L_d) + (C R + L_m) = 2 C R + L_d + L_m$. If the speed of the motor be *greater* than that given by these equations, L_m, the only quantity that can possibly be varied, must be a factor of importance, and, moreover, of *negative sign*. This means that, in the motor, the armature adds magnetism to the resultant field, and thus increases the value of E_m, and consequently raises the speed. In the limit $L_m = C R$ and $E_T = E_m$—*see* (II). Even if these values were possible in practice, E_m would be still less than E_d; so that the relative values of the speeds can only be seen by examination of the ratios $\frac{E_m}{n_m}$ and $\frac{E_d}{n_d}$. It will be found with all normal machines that $\frac{E_m}{n_m}$ is less than $\frac{E_d}{n_d}$. One must not confound the question of efficiency with these experiments. The efficiency of a dymamo for a given E.M.F. and current varies *inversely* as the speed, for the torque is clearly proportional to some function of the current, and is nearly independent of speed. The motor efficiency for the same electrical constants varies *directly* as the speed. In fact, we endeavour to make the dynamo speed a minimum and the motor a maximum.

In the first experiment, say in a large Edison-Hopkinson dynamo, the efficiency either as dynamo or motor will not differ much, but I should expect the motor to give the better result by a small percentage. The influence of the armature is relatively small, and the lead very little. The only objection to the machine considered as a motor is the weight, and consequently, increased cost of material for a given output.

In the second experiment the armature is large compared with the field. Hence, the lead as a dynamo will be great—probably 30 degrees at least in a positive direction; as a motor the lead, if any at all, will be much less, perhaps 5 degrees in the negative direction. The machine will be inefficient as a dynamo, and require a high speed; but as a motor it will be *much more* efficient, though the speed will not be so great as that required for the dynamo. The second machine will be a good motor, efficient, light, and cheap.

This explanation is very rough, but it will help to explain the reason for considering the armature as an independent magnet in motor design. The Oerlikon plant, described in the technical press some six months ago, illustrates the point. The dynamo and motor have armatures identical both as regards the mass and distribution of iron and copper; but the motor field has 7 per cent. less copper and iron than the dynamo, and I know of many installations where proportionately much smaller motor fields are used with advantage.

Many attempts have been made to predetermine the characteristics of dynamos and motors; yet the best seem to be but approximations. From what has already been said it follows that the difficulty only lies with the number of lines of force in the field. This quantity is indeterminate, chiefly because we have no magnetic insulator. We can get the characteristic of the iron of both field and armature, and we know the resistance of the air-space. But we do not know and cannot as yet predetermine by calculation the loss of magnetism which will take place over a new type of machine. Mr. Kapp has shown that this leakage is a function of linear dimensions of the machine, and hence varies with every type; indeed, no matter how small the alteration in design the value of the lost magnetism is changed. Practically this presents no difficulty, as only a few types obtain with most firms, and a few simple experiments will determine the number of ampere turns to give any desired result.

The Brothers Hopkinson and Mr. Kapp were, perhaps, the first to move in this direction of calculating the ampere turns required in the field to give a definite magnetic flux in the armature. Both methods are well known, but a brief reference will assist us to follow the subject. Mr. Kapp started from a geometrical treatment of the design, and assumed the magnetic resistance of iron to be expressed by a law similar to that of Ohm, and the saturation effect was assumed to follow a tangent function. I have used the Kapp formulæ for many machines, both dynamos and motors; indeed, I think I was probably the first to apply them to motors; but the results are not satisfactory, particularly with large machines. The equations do not take into consideration the leakage in a sufficiently accurate manner, and the ampere turns have to be increased from 25 per cent. to 100 per cent. above the value given by calculation. The characteristic thus obtained usually rises too slowly, and after cutting the real curve about the point of half-saturation of the field-magnet, does not fall sufficiently rapidly. My experience, I believe, is fairly well borne out by other users of the Kapp formulæ.

Hopkinson starts on a different basis. He determines experimentally the curves of saturation of both field and armature iron, and expresses the magnetic flux in terms of absolute magnetising force $\left(\frac{4\pi S i}{10}\right)$ turns per centimetre length of core. The specific resistance of air is also determined by experiment. So far this is perfectly safe ground. But the characteristic of the machine itself is the summation of the curves of the field and armature iron and the air space, modified by the leakage and the reactions of the armature. Hopkinson has now to resort to experiment to find the magnitude of these disturbing influences, and a good deal of approximation or experimenting

Digitized by Google

is required ; indeed, the method is not applicable to a new type of machine without considerable knowledge of the subject.

Prof. Silvanus Thompson, in the third edition of "Dynamo-Electric Machinery," gives a method combining both Hopkinson's curves and Frölich's equation :—

$$N = N_1 \frac{S\,i}{S\,i + (S\,i)_1}.$$

N = maximum number of lines in field-magnet.
N_1 = lines in field-magnets to give the diacritical value.
$S\,i$ = ampere turns to give N.
$S\,i_1$ = ampere turns to give N_1.

But this, again, demands an experimental determination of the leakage coefficient, and does not seem to me to advance the subject much.

Mr. Esson employs a modification of Dr. Hopkinson's method. Using the saturation curves of the iron and specific resistance of the air as his starting points, and selecting a definite value of Z_a, he determines the number of ampere turns per centimetre of magnet core to give this value in the armature, neglecting leakage or self-induction. With a known type of machine this method presents great advantages, for the field-winding is given by simple reference to the curves.

Fortunately for us practical men there is no pressing need of an exact mathematical solution. With a known type of field, machines of any output can be designed with certainty from previous experience, and easy applications of the rule of three.

It may be noted that the slope of the characteristic is mainly determined by the resistance of the air gap. The curves of the field and armature iron do not largely affect the general shape till the diacritical points of either be reached. If the field be so crowded with wire that this point be passed, then the characteristic of the machine will bend rapidly.

Before leaving this part of the subject, I will briefly examine the question of pole-pieces.

Judging from the variety of shapes of polar extensions obtaining in machines in the market to-day there seems to be no little ambiguity on the subject. Some makers use long poles, extending over nearly 160 degrees of the armature periphery. Others cover 90 degrees to 100 degrees. Some machines are to be found with long, thin, sharp extensions, whilst some have short, thick, and rounded ends. Each in its way accomplishes a particular end, but only want of knowledge could lead to the extreme proportions sometimes met with. This variety of dimensions in the pole-pieces and extensions arises from an attempted compromise between theory and simplicity of design.

Theory, on the one hand, points to an extended pole-piece if a low magnetic resistance of the air gap be desired. But since there is a tendency for the magnetic density to increase at the extremities of the poles, an undue lengthening of the arc encircled leads to a distortion of the main field. And, further, the position of commutation becomes a line, whilst really there should be some two or three segments on either side on which the brushes may rest without causing sparking or heating of the coils short-circuited beneath them.

Theoretical considerations, then, compel us to shorten the polar extensions, although we thereby raise the total magnetic resistance. This involves, however, no practical loss, for magnetism is cheap, and a few more ampere turns will compensate for the weakened field.

It is curious to note how the tendency to shorten the pole-pieces has increased during the last twelve months or so. The Manchester dynamo used to have pole-pieces extending over 139 degrees. I heard the other day of a Manchester machine with poles not more than 90 degrees in length. Messrs. Paterson and Cooper are also making both dynamos and motors with short poles ; so are many other firms.

In some designs there are practical reasons for shortening the poles. If the cores are vertical, it is a convenience to be able to slip the windings over the coils. To attain this the cores are prolonged and the poles bored out of them, instead of being built up of separate castings. This is applicable to both cast and wrought iron magnets.

Rounded polar extensions are also used in some designs, particularly with high-tension machines. I think this was first done in the Weston dynamos. Speaking generally, for motor pole-pieces I would recommend that the arc embraced be not more than 120 degrees, preferably rather less, and that the poles be rounded at all their extremities. The section of the poles should vary about in proportion to the magnetic flux desired. By a careful attention to this point the field may be properly spread over the whole of the coils beneath the poles, and the E.M.F. induced per coil be approximately the same. This is a matter of no little importance in large machines.

The best way of testing the activity of the different coils is the one first used by Mordey, I believe. By a simple arrangement of two movable brushes, the E.M.F. of coils in different parts of the field is successively measured and the result plotted. This gives the differential curve of potential. From this the integral curve may be obtained, or a direct experiment will give the same result. Fix one lead of the voltmeter to, say, the negative brush, and move the other in contact with the commutator through spaces equal to the angular width of one coil, taking readings at each space. These two curves show at a glance the relative activity of the coils and the distribution of the main field. No better method can be devised for showing the exact action of the armature, and the relative advantages of differently shaped poles and polar extensions are at once apparent.

This method is also very useful for showing the difference between the distribution of magnetism in the dynamo and motor field. I have derived considerable assistance from an exhaustive treatment of different machines in this manner. The results obtained are very curious, and serve to explain why it is advisable to make a difference between machines used as dynamos or as motors.

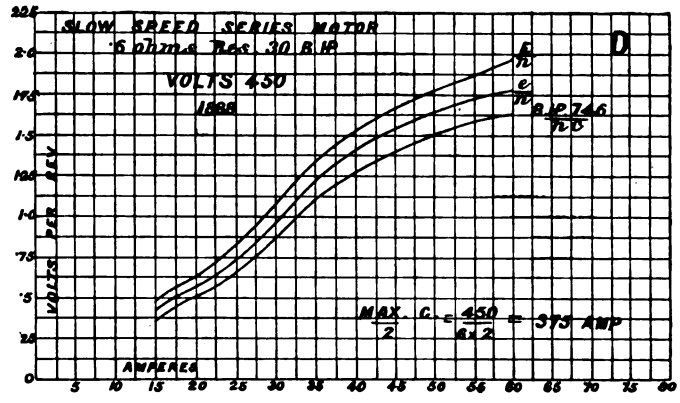
Generally motors are likely to have greater and more sudden variations of load than dynamos, hence the necessity for extra care in designing the pole-pieces. The principal point to be aimed at is to make the position of commutation sufficiently large for the variations likely to occur.

Assuming we have now designed and built our motor on the lines discussed here, it will be necessary to examine the degree of excellence attained. This is best done by brake tests. It will not be necessary to run the motor at a constant potential ; indeed, in practice this is often a matter of no little difficulty. Let our motor be series-wound, and designed to run on a lighting circuit of 100 volts. Measure the ohmic resistance hot. Arrange the motor with a Prony or other absorption brake, and put a suitable resistance in series with the windings, so that any desired E.M.F. may be obtained within the limits of supply.

First, run the motor light—*i.e.*, without the brake, at the highest speed required of it, and note the terminal volts and the amperes. Then place the brake in position and screw down the blocks. Take readings with different loads, varying the current by intervals of one ampere, and noting the corresponding volts and speeds. When the maximum load is reached, we have all the data for calculating the performance of our motor. Arrange ten columns with following headings :—

Speed.	Weight.	Volts.	Amp.	B.H.P.	E.H.P.	Efficiency.	$\frac{E}{n}$	$\frac{e}{n}$	$\frac{\text{B.H.P. } 746.}{n\,c}$

The first four are filled in from the observations of the test. The B.H.P. is calculated from the speed, the brake load, and the brake constant. The E.H.P. and the efficiency speak for themselves. We have now three columns left. From these we purpose to plot three curves that will show how far our method of design be successful.



The first, $\frac{E}{n}$, is the terminal E.M.F. divided by the speed obtaining for the particular value of E.

The second, $\frac{e}{n}$, is the so called back E.M.F. ($= E - C\,R$) divided by the same value of n.

The third, $\frac{\text{B.H.P. } 746}{n\,c}$, is really of the same order, viz., a definite number of volts absorbed per revolution *in actual work on the brake*.

This requires some explanation. Note that the B.H.P. multiplied by 746 gives the available useful horse-power in watts, *i.e.*, a quantity that can be expressed by the symbol C E. We know the current flowing for any load, but do not know the exact fraction of the applied E.M.F. usefully employed for external work. But if we divide the B.H.P. expressed in watts

Digitized by Google

by the known currents, the value of the unknown volts is given. This quantity is divided by n to reduce it to volts per revolution. The efficiency is thus given us by dividing $\frac{\text{B.H.P.}\ 746}{n\,c} / \frac{E}{n}$, or efficiency $= \frac{\text{B.H.P.}\ 746}{c\,E}$. We now take a piece of squared paper, and set off the current as abscissæ, and for ordinates the volts per revolution. Then we plot against the several currents the corresponding values of $\frac{E}{n}$, $\frac{e}{n}$, $\frac{\text{B.H.P.}\ 746}{n\,c}$. This gives us three curves. Two of these rise from the origin 0; but the third, the curve of useful work, starts at that particular value of c which is just sufficient to overcome the static resistance of the motor. It will be noted that these curves tend to diverge from parallelism as the load increases. They show on inspection two things of great importance in motor design. The height of the ordinates between $\frac{E}{n}$ and $\frac{e}{n}$ show the E.M.F. lost over the ohmic resistance of the machine when heated to its normal temperature. The distance between $\frac{e}{n}$ and the lowest curve $\frac{\text{B.H.P.}\ 746}{n\,c}$ shows the E.M.F. lost from all other causes, viz., material and magnetic friction, and by induction. These three curves give at a glance the value of the motor as a converter of energy, and they show not only where the losses occur, but they give the magnitudes. The several quantities are divided by n, simply because it is practically difficult to make a test with constant speed. Since n is proportional to $\frac{\text{B.H.P.}\ 746}{n\,c}$ and is the same for the three ordinates corresponding to each value of c, no error of importance is introduced.

We now can see whether the losses, other than those due to the internal resistance, are excessive. The heat waste is a necessary evil, and can only be reduced within certain limits. The area between $\frac{e}{n}$ and the work curve can, however, be made very small. In a really well designed motor this area should always be considerably less than that proportional to $C^2 R$.

If the losses due to friction and Foucault currents be larger than those caused by the copper resistance, the machine is badly designed. Our motor, however, will not only have a small value for $C^2 R$, but its other losses will not exceed $\frac{C^2 R}{2}$.

With these rough notes I close my Paper. I may not have told you much that is new, but I hope to have made clear some of the more general difficulties, and to have put the design of motors on a simple engineering basis.

READING THE BAROMETER AT A DISTANCE.

The following apparatus for reading the barometer at a distance has been devised by M. G. Kornmüller, of Ghent. Fig. 1 shows

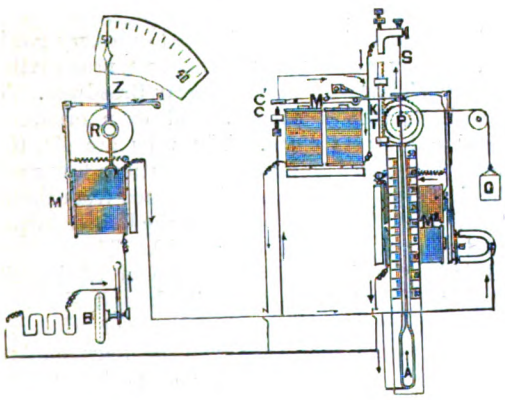


FIG. 1.

FIG. 2.

the receiving instrument, and Fig. 2 that at the distant end. On depressing the key B the current from the battery flows through the magnet M′ and the ratchet wheel R, carrying the pointer; Z is thereby advanced one tooth. The current also passes at the same time through M^2 at the distant end, and the ratchet wheel P is also advanced one tooth. By a "trembling bell" arrangement on M^2 the current is made and broken continuously, and the two ratchet wheels therefore rotate synchronously. T is a rack gearing with a pinion attached to the ratchet-wheel P, and by its rotation is pulled downwards against the action of the counter-weight G. This rack carries a platinum wire, S, which fits loosely into the thermometer tube A, the mercury in which is connected to the circuit as shown. As soon as the wire touches the mercury it makes the circuit of the magnet M^3, which, attracting its armature, lifts the catch K, and the rack and wire are at once raised again by the counterweight G. M^3 being made of much lower resistance than M^2, takes the greater part of the current, and M^2 is rendered inoperative; the make-and-break action, therefore, ceases, and the pointer at the receiving end remains at rest, indicating the height at which the mercury stands at the distant station. In short, when the key is depressed a make-and-break action is set up, advancing the two ratchet wheels synchronously until the wire touches the mercury, when the indicator stops, and the mechanism at the distant end resets itself. In order to avoid a spark when the wire leaves the mercury it will be seen that as soon as the armature of M^3 is attracted it makes its own circuit at C C′ independently of the mercury. The push button B is arranged so that releasing it mechanically resets the pointer to zero.

LEGAL INTELLIGENCE.

In re Gaulard and Gibbs' Patent.

COURT OF APPEAL.—SATURDAY.

(Before LORD JUSTICES COTTON, LINDLEY and LOPES.)

This is an appeal of Lucien, Gaulard and others against the judgment pronounced by Mr. Justice Kekewich on July 9th, 1888*, in the case of a petition for the revocation of certain letters patent which were granted to Messrs. Gaulard and Gibbs on the 13th of September 1882.

Mr. Aston, Q.C., and Mr. J. C. Graham appeared for the appellants, Messrs. Gaulard and Gibbs; and Sir Horace Davey, Q.C., and Mr. Fletcher Moulton, Q.C., for the plaintiff, Mr. Sebastian Z. de Ferranti.

Mr. ASTON, in opening the appeal, said that the hearing in the Court below lasted some time, and eventually the learned judge came to the conclusion that for want of good subject matter the patent was bad, and therefore ought to be revoked. His lordship also said, though he did not give a special judgment on the point, that the invention as described and claimed was wanting in novelty, and the learned judge especially referred to the specification of Harrison. Against that judgment Messrs. Gaulard and Gibbs now appealed. He should endeavour to show that that judgment was erroneous, for the following reasons:—First, that Messrs. Gaulard and Gibbs described clearly in a sufficient specification a new and useful system or process of distribution of electricity from a central supply station to local stations placed on a long main wire. Secondly, that no prior use of such a system had been, or could be proved, because it did not exist prior to the date of the patent. No prior description could or had been produced which without important alterations or additions could be made to fit the description of Gaulard and Gibbs' patent. His third point was that the Court below had been misled by applying what had been called the mosaic construction, and assuming that Messrs. Gaulard and Gibbs had used parts of prior publications. His fourth point was, that the learned judge in holding that the patent of Gaulard and Gibbs was bad for want of good subject matter, failed to give proper effect to the uncontroverted evidence given on that occasion. The learned judge had mainly based his judgment upon alleged want of subject matter in the patented invention.

The problem to be solved is this: There being a central station at Edgware-road, how was electricity to be distributed along a main wire so as to supply local installations on a line, for instance, of fifteen miles. Up to the date of the patent in 1882 there was no way of doing it. There had been no described way of treating anything like a line of fifteen miles by supplying from a central station electricity which was to be taken to stations 1, 2 and 3 along the line at two, three, or five miles interval. The first thing to be done was to state what was the generator to be employed. Dynamos sending alternating currents were known, and these would do provided they had those alternating currents of high tension. Anybody at the time of Gaulard's patent might have gone wrong; and so far the majority of the so-called anticipations did go wrong, because one said he would have his generator a battery, another a magneto-electric machine with direct current, and another that he would have an alternating machine, but he did not say what kind of current. He (the learned counsel) would prove that high-tension currents were required, and alone would do. When they came to his learned friend's chief witness (Sir Wm. Thomson) they would find that in order to send a pressure along a main wire to supply installations at long distances, they must have a high tension of at least 2,000 volts. However, the problem was not solved by simply telling the world what was the right generator, and that they must have a long main wire along which to send that electric energy, for Sir Wm. Thomson told them that 2,000 volts was a man-killing energy; and Sir William said that 200 volts was the highest amount that they could employ for the purpose of lighting houses or shops. But there was another reason: The voltage required for the incandescent lamp varied in the Swan from 50 volts to 100 volts in the Edison, but none of them went above 200 volts. They could not send through those lamps the same current that it was absolutely necessary to employ in order to send their current through 15 miles of wire. How was that problem to be solved? The patentee told them. Place at intervals along their main wire a secondary generator of a special character. The machine itself must supply the currents at a potential to supply electric energy for fifteen miles, and which drove it with a velocity that alternated 16,000 a

* See *The Electrician*, July 13th, p. 316.

Digitized by Google

minute. That electricity would not do for local installations, but that electricity would induce at the local stations a suitable current which might be there safely utilised to do the work if they had a proper secondary generator. Induced electricity was electricity set up in a collateral wire by variations in the electricity which was allowed to pass through a main wire alongside of which the collateral wire was laid. The resistance of the secondary wire was very much greater in the Ruhmkorff coil, because the resistance increased as the area diminished. The patentee had to solve the problem of supplying lamps of various characters at various stations more or less. Consequently they had to do two things, they had to describe an induction coil of a special character that could be adapted to various installations, and to glow lamps and arc lamps. They must have a secondary generator capable of adaptation, not like the Ruhmkorff coil, which once made up was made up for all time. They must have them so that the induction coils themselves should not set up in their cores local currents that were injurious. Although the patentees had not claimed secondary generators, still they had indicated the kind of secondary generators that must be used to make it a success, and the kind of electricity as regarded its condition that must be sent along these wires. When that system was put forward in a practical form, and when the electric lighting world was told that that solved the problem it, was not accepted, but it was received with doubt and incredulity and ridicule. He would tell their lordships why. Sir William Thomson pointed out that wherever they had induced electricity to do that, and they caused that induced electricity to manifest itself. by a current going through a primary wire, they had to pay for it. Consequently a doubt which pressed upon the minds of electricians was, if they had an alternating current of 2,000 volts sweeping from pole to pole of their dynamos to and fro, and they tapped that energy at local stations by using secondary generators or induction coils, they would not get anything like the energy they wanted in these induction coils. That was the way in which scientific persons received the statement that these secondary generators could be so constructed as to employ the induced electricity excited at the local installations to do local work. But the thing was done at the Aquarium and at Edgware-road. At the latter place they had a dynamo machine, sufficient alternating currents, and a main wire 15 or 20 miles long; and there were four or five local installations, and 50 to 100 lamps, and they all worked. Dr. Hopkinson gave in evidence that he found the return in energy in the secondary generators made and used by Gaulard and Gibbs as 86 per cent. The moment Dr. Hopkinson told the world that the patent was a success what happened? Why, what always happened. Rivals said that they had rummaged among the Blue Books, and they had found it there anticipated. These rivals could not find a single instance of its practical application. His learned friends would refer to seven or eight patents as disclosing an anticipation of his clients' patent; but, whilst they contained some part or some element of the combination, he submitted that not one of them had the combination. The specification of Messrs. Gaulard and Gibbs, as it originally stood, was open to objection by reason of a doubtful interpretation that might be put upon the language there used. Consequently, their lordships would find that certain lines were struck out by disclaimer, and the claim to the secondary generators as a separate element was also disclaimed. The title of the specification was "A New System of Distributing Electricity for the Production of Light and Power." It was not a new system of generating electricity; it was not a new system of lighting; but it was a new system of distributing electricity for the production of light and power. There was a very sharp distinction between a system of distribution and a method of lighting a single lamp or a group of lamps. The complete specification said, "This system consists of the employment of an alternating current produced by an electrical dynamo machine, and determining by its passage through a number"—it originally stood an unlimited number—"of electrical generators of special construction. The formation of induced currents of the requisite kind, on which the quality and value"—that was to say the quality and value of the currents—"depend only on the construction of the secondary coil, and the several electrical generators."

LORD JUSTICE LINDLEY: Do your opponents say that this alteration or disclaimer extends the right?

Mr. ASTON: No; they cannot say that, because Mr. Justice Kekewich told them that they had not put in the pleadings.

SIR HORACE DAVEY: I do say that the amended specification treating that as if it was the original specification was of a different kind of invention from that described in the provisional specification.

Mr. ASTON: I say that my friend has no cross appeal, and the learned judge has decided that in my favour.

LORD JUSTICE LINDLEY: Did the learned judge go into that point?

Mr. ASTON: Yes. Let us suppose that I am open to that. I say that the statement "unlimited" may fairly be construed as indefinite—that is to say, not limited to any precise number. If unlimited were construed as limitless, then it would be untrue. The learned counsel then proceeded to say that the petitioner objected to the amended specification because, first, it was not useful; second, it was not new; and, third, that it was not the subject matter of a patent. He did not think that they heard anything about the sufficiency of the specification.

Sir HORACE DAVEY: Oh! Where do you show the class of secondary generators?

Mr. ASTON: It is a secondary generator which has a divided core so that Foucault currents should not be there. It is a secondary generator which consists of secondary or primary wires, and secondary wires having convolutions in juxtaposition, so arranged that you can suit them to the varied work which they would have to do in the varied installations. My friend says that is not so.

Mr. MOULTON: That was not suggested in the Court below.

Mr. ASTON: We said that we believed for the first time that the secondary generators made by Gaulard and Gibbs were connected with an alternating dynamo on a long main wire. Am I right in saying that these secondary generators do consist of primary wires and secondary wires with varying convolutions? Sir Horace Davey interrupts me and says "They all do." I say they do not. Then I say that they must have divided cores, and nobody said that they must have divided cores. I challenge my friend to point out a single person who said: "Now mind when you use an alternating dynamo at high tension, take care that your induction coil has divided cores." There is not a single instance of user in one of the seven or eight prior specifications put in. Sir Wm. Thomson, Mr. Ferranti, Dr. Fleming, and everyone of the witnesses were asked, "Did you ever see one of those crude anticipations," and they said "No."

LORD JUSTICE LINDLEY: You say that the central exciting core is a divided core.

Mr. ASTON: Yes; and Sir William Thomson says the same. When I come to Sir William's evidence you will find that he distinctly says that solid and divided cores were known. There was a man named Fuller, a well known electrician in the United States, who took out a patent under the name of Lake, and that patent was relied upon as an anticipation. But it is very remarkable that where there is any reference to an alternating current supplied by an alternating machine, the core of the induction coil is always solid.

Mr. MOULTON: You own chief witness said it was not.

Mr. ASTON deprecated these interruptions.

LORD JUSTICE COTTON asked if Sir Horace Davey was going to say anything about the specification as amended by disclaimer.

Sir HORACE DAVEY: The particular form of objection which I took was this: Assuming that the specification as now amended was the original specification which had been originally filed by the patentee, it describes an invention different from the provisional specification.

Mr. ASTON argued that in that case his learned friend should have gone for a cross appeal.

Their Lordships intimated that Mr. Aston would have to meet Sir Horace Davey's point; and the Court then adjourned.

SECOND DAY, THURSDAY.

Mr. ASTON resumed, addressing himself to the objection that the specification failed, as the complete specification was not in conformity with the provisional specification, and argued that there was no substantial distinction between the wording of the provisional and complete specifications, and that therefore the objection was bad in law. The learned counsel then read over the judgment delivered by Mr. Justice Kekewich, and the Court adjourned at luncheon time for the day.

Mr. ASTON then proceeded with the reading of the evidence of Dr. Hopkinson, the cross-examination being read by Sir HORACE DAVEY.

LORD JUSTICE COTTON observed that certain things were supposed to be claimed because they were necessary to success, but it appeared from the evidence that the patentee (Gaulard) did not know they were necessary. Under those circumstances, it was a question whether he had given a sufficient description of the invention in his specification.

Mr. ASTON: That, my lord, I shall have to deal with by-and-bye.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *January 5th*, 1889.

The local Edison Illuminating Company has just begun to supply current from its up-town stations, and from this time the capacity of the plants will be gradually increased until they reach their limit. The two buildings, which are almost exactly alike inside and out, are situated in a very good section of the city, one being in Twenty-sixth-street, near Sixth-avenue, and the other in Thirty-ninth-street, near Broadway. They are five stories high, with a massive and even ornate front of granite, brick, and terra cotta. The walls are 4ft. thick, and nothing has been spared to render the stations fireproof. Some idea of the fireproof qualities may be formed from the fact that in a total cost of $140,000 for building, the bill for carpentering, glazing, and painting is less than $4,000. The stair ways are stone and iron, the floors and roof are of tiled arches, and the sidewalls are lined with glazed brick and slate. Taking the Twenty-sixth-street station as a sample of what is done in both, it may be stated that there will be fourteen Armington and Sims engines, 250 horse-power each. Both of these engines will run two dynamos, making twenty-eight machines in all, each capable of supplying 1,250 16 candle-power lamps, so that the total capacity will be some 35,000 lights actually running at one time from each station. A remarkable feature of the plant is the manner in which the different departments are arranged. The boilers, for instance, are on the third floor; the water tanks are immediately above, and the coal pocket is on the top floor. The pocket will hold 1,200 tons of coal, and it is so arranged that coal is delivered from it by a shoot in front of any two boilers, in such a way that there are never more than a few shovelfuls of coal on the floor of the boiler room. The water tanks are of equally large capacity, and will hold, I

Digitized by Google

believe, more than a full day's supply. On the second floor in the middle is the general workshop and the meter room, and at each side are the depositing ashpits of the boilers. This is a very neat arrangement. Immediately under each boiler, on the floor above, is a hopper with a bottom which opens by a lever. Under these hoppers runs a little railroad track, up and down which travels a small ash car. Once a day the hoppers are emptied into the car, which is then brought to the front of the building along the track, and is emptied into another hopper opening into a passage leading into the street. From these larger hoppers the ashes are dumped into a cart once a day and carried away. As they have been previously damped there is no dust, and the whole system works like a charm, there being no shovelling of the ashes at all. In the dynamo room the dynamos are grouped in pairs along each side, and the controlling and regulating apparatus is brought together on the central platform or gangway, up and down which the attendant can walk, with every dynamo and instrument in full view. For the distribution of the current that is generated in this and the other station about 165 miles of conductors have been laid. The company are so well satisfied with the prospects that they have purchased ground for another station a mile or two further up town, in Fifty-third-street, not far from Central Park.

You may remember that the United States Illuminating Company brought a suit recently against the Board of Electrical Control to obtain an injunction restraining the Board from interfering with its wires. Judge Lawrence, of the New York State Supreme Court, says that, after the examination of the papers in evidence, he is of opinion that the company is not entitled to an injunction, and that he "sees no reason for interposing the strong arm of the law to arrest the progress of a great public work, the speedy completion of which is desirable for the safety and convenience of the people." This is pretty conclusive, and when it is taken in conjunction with the advent in office of the new Mayor, who supports the Subway Board, it will be seen that matters are likely to go hard with companies that will not acquiesce quietly in the new order of affairs. While the attitude of the Court and of the Mayor may be altogether such as the law requires, it is a great pity that the conduits are not so good as they might be, for then there would be much less opposition to their use. The second annual report of the Board of Electrical Control to the Governor states that a total length of 240,155ft. of trench has been excavated in this city for the laying of subways. It is estimated that the total capacity for telegraph and telephone service is 34,655 miles of wire, and that the capacity for light and power service is nearly 600 miles of wire. These figures are exclusive of the Edison underground service, which, though under the jurisdiction of the Board, has been laid independently. The Board reports that it has removed 776 poles and 946 miles of wire. The companies that have gone underground are now operating 4,453 miles of wire. The report admits that there has been an increase during the year in the mileage of overhead conductors; but it points out that there has been a great increase in electrical service, the growth in electric lighting alone being estimated at more than 200 per cent.

The reference I have made above to the fine new electric light stations in this city reminds me that an addition has been made to the list of telephone palaces. New York, Chicago, and other cities have splendid exchange buildings, and St. Louis now falls into line. The Bell Telephone Company, of Missouri, have just adopted a plan for the erection of a building in St. Louis, which is to cost $125,000. It will be seven stories high, and will be built of stone, rough dressed, presenting a most handsome and solid appearance. It is the intention to rent out the first five stories and part of the sixth. The executive offices of the Telephone Company are to be on the sixth floor, and the whole of the seventh floor will be occupied by the exchange room and its adjuncts. Under the skilful management of Mr. Geo. F. Durant, the telephone service in St. Louis on the Law system has grown very rapidly and has been very efficient.

The daily *Graphic* of this city, which is, I believe, the only illustrated daily paper in the world, has just printed a very interesting article on electric power, taking for its theme the growth of the Daft Company and the work of its electrician, Mr. Leo Daft. It may not be generally known that, as appears from this article, Mr. Daft is an Englishman, who was born in Birmingham in 1843. When the family moved to London the boy early showed an interest in electrical matters and other devices, and came under the notice of Mr. Siemens, who took an interest in him and helped him along. Mr. Daft came to this country as a civil engineer, and after engaging in railway work, started a small electrical factory at Philadelphia. In those days there was no great demand for electrical apparatus, and he went into other work until 1880, when the renewed interest in electric light and power gave him a new opportunity of which he did not fail to avail himself. Through the instrumentality of the Daft Electric Light Company, Mr. Daft now has the advantage of large works at Marion, N.J., and has been enabled to take no small share in the development of electric power in this country. Daft motors are in use in every part of the Union, and it is said that in this city alone some 1,500 horse-power is developed through their instrumentality. There are also Daft electric roads running at Baltimore, Los Angeles, Pittsburg, Meriden, Mansfield, Asbury Park, Ithaca, Easton, and elsewhere, as well as the experimental section of the Ninth Avenue elevated road in this city upon which the motor, "Ben Franklin," of which an illustration was recently given in your columns, is operated.

Now that the law has gone into effect requiring that electricity shall be used in this State as the means of capital punishment, the newspapers are busily engaged discussing the *pros* and *cons* of the subject, and expressing their views as to the feasibility of the law. As regards the parts of the law which provide that none of the newspapers shall give details of these electrical executions, it is safe to say that they will be a dead letter from the outset. The newspapers are determined that they will record such executions as fully as they would those of any other method, and they denounce as unconstitutional the clause which says that they are to be punished if they endeavour to gratify the curiosity of their readers. Such a provision acts simply as a stimulus to our enterprising newspaper men, just as it would to those in England, and the reports are likely to be fuller from the fact that they are forbidden. With respect to the plan by which the sentence shall be inflicted, great doubts still seem to exist as to the best course to be adopted. Among electricians here, the idea of using electricity for this purpose is not relished, and one cannot blame a body of men for resenting anything that may tend to lower the dignity and status of their profession. You have already published some of the plans proposed, including that of the Medico-Legal Society, which in some way has been constituted a kind of adviser on the subject, and has given evidence that, while it may know something of medicine, it does not know too much about electricity. The *Electrical World* has expressed its opinion against the plan that has been recommended, and the *Electrical Engineer* is also opposed to electrical executions. When a man is about to lose his life it is little enough to ask that he should be allowed to die in a gentlemanly way, but it would seem that electrical execution would reduce the criminal to the level of the merest brute under torture of uncertain severity and duration, and would turn the representative of the State inflicting the last dread penalty into a person who is, perchance, risking his own life, and subjecting his profession to unnecessary odium. The whole matter is in bad shape, and as we have already one or two candidates for the executioner, it is doubtful how they will be disposed of. As the *Scientific American* says, "The law has been passed, and no provision has been made to carry it out. Apparatus is not provided, no competent specialists have been appointed to superintend its administration, and in the present state of affairs the present law appears to amount to little more than in indefinite suspension of the death penalty for murder."

An important suit has been brought in the State of Pennsylvania by the State officers against the Western Union and Baltimore and Ohio companies for consolidating. It is alleged that the charter of the Baltimore and Ohio Company in Penn

Digitized by Google

sylvania contained a provision that the company should not be sold or consolidated with any other company, and on that ground the Attorney General claims a decree of forfeiture and escheat of the lines, property, and franchises of the Western Union Company in that State. In some quarters it is believed that this move is due to the recent triumph of the Garratt interest in the election of the new president of the Baltimore and Ohio Railway Company; but it is stated, on the other hand, that the Attorney General has taken the step of his own free will, and would have moved in the matter over a year ago had he been in possession of positive proof establishing the fact of the consolidation. Dr. Norvin Green, the president of the Western Union Company, takes the matter placidly, and says that there is no good ground for the action. He holds that there is no actual consolidation, as the Baltimore and Ohio organisation is still maintained separate and competing. Moreover the Western Union Company, when it made its purchase of the Baltimore and Ohio plant, did not buy that portion that was operated in the Pennsylvania charter. The Pennsylvania Company was not included in the purchase as such, and the Western Union expressly refused to buy it on account of the stringent State charter. Furthermore, Dr. Green says that if the State law is invoked in this case it would have no effect in the face of the United States law, the United States Supreme Court having decided over and over again that telegraph business comes in the category of inter-State commerce, and cannot be interfered with by State action or statute.

CORRESPONDENCE.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: At a recent meeting of the Society of Telegraph-Engineers and Electricians a discussion was raised by Mr. Preece on the present method of electing the Council of the Society. It happens that I have devoted some thought to the subject, and as there is little or no probability of the discussion being resumed, I ask to be allowed to give a short statement of my views in your columns.

Instead of adopting the practice followed by nearly every other learned Society, of recommending for election only a sufficient number of persons to fill the vacancies, the Council has, of late years, submitted lists containing many more names than are required for the purpose, leaving it to the members themselves to make a selection from those nominated. Mr. Preece said that there was a difficulty in finding men of eminence and position who would submit to this process of competition. I am not surprised to hear it. Many such men, however highly they might value the honour of a seat upon the Council, would no doubt object to be put into public competition for it under any circumstances whatever. But when we consider the actual conditions of the competition their hesitation to take part in it becomes even more intelligible.

It implies no want of respect to the gentlemen whose names are contained in the list of members and associates to say that the great bulk of them are, as individuals, quite incompetent to appreciate the relative qualifications of the several candidates for election. With such an electorate it might well happen that the inventor of a widely-advertised ampere-meter, for example, would stand a better chance of success than a man whose claims were of a far more solid and substantial though less popular character. The latter might naturally be unwilling to court rejection, which, even if it did him no serious harm, would at all events not add to his reputation.

But it is not only, or mainly, from the candidate's point of view that I take exception to the method at present in vogue. I consider that in adopting it the Council are shirking their responsibilities, and seeking to relieve themselves of a part of their reasonable duties. The position which they hold in the society, together with the opportunities they have of organised discussion and inquiry, give them immense advantages in adjudicating upon the relative merits of possible candidates. If they know who are the best men to fill the vacant seats, they are bound, in the interests of the society of which they are trustees, to name them. If with all their advantages and opportunities they are unable to decide, how can a mere private member be expected to do so? For my own part I decline to make the attempt, and straightway consign my balloting list to the waste-paper basket.

The present system was avowedly designed to meet the dissatisfaction which was somewhat freely expressed a few years ago with regard to the constitution of the Council. As a matter of fact, it does nothing of the kind, and if the former state of dissatisfaction no longer exists, its disappearance is due to other causes. What was, I think, reasonably objected to was the persistence with which certain members of the Council (useful and able men, no doubt) clung to their seats year after year, to the exclusion of others equally competent. A frequent and liberal infusion of new blood is for many obvious reasons desirable, and I believe it would be an excellent thing if the custom were established of placing upon the balloting list the names of only a bare majority of the existing Council, thus limiting the average tenure of a seat to a term of about two years. By this course not only would the Council be brought into more intimate and harmonious relations with the Society generally, but it would become possible to distribute the honours, the dignities, and (let us be candid) the commercial advantages of office among a larger proportion of its members.

There is another matter in which I think reform is sorely needed. The volumes of our *Journal* constitute a vast treasure-house of exceedingly valuable matter; but it can hardly be denied that they are at the same time the receptacle of an appalling amount of inane trivialities, not to say downright rubbish. This is the consequence of the practice of reporting discussions *verbatim*. At the Royal Society no report whatever of a discussion is permitted. It was found that so long as the learned Fellows were exposed to the liability of having their unconsidered words taken down in writing, they hesitated to speak at all, and reporting was prohibited in order to promote freedom of discussion. It is possible that a few (very few) words of wisdom may have been lost to our own Institution from a similar cause; but with us the evils resulting from copious reporting are, generally speaking, of quite the opposite character. Men who, having nothing to say, would in the absence of the reporter wisely hold their peace, cannot resist the opportunity which the *Journal* offers of "keeping themselves before the public," especially when from a business point of view there is something to be gained from publicity. Having no information to impart with reference to the subject in hand, they are content either to reiterate the remarks of previous speakers, or to enlarge upon any irrevelant topic that occurs to them.

The remedy is simple. We cannot afford to dispense altogether with reporting, for there are many speakers (including some of those who speak most frequently) whose remarks are always well worthy of being recorded. But the shorthand writer's transcript, instead of being printed in its entirety should be submitted to a competent sub-editor, whose duty it would be to separate the wheat from the chaff, and to prepare short summaries of all except the most important speeches. In nearly all cases considerable abbreviation would be advantageous; in not a few it would be possible to give the pith of several pages of verbiage in as many lines. If this were done, not only would the standard of our discussions and of our journal be improved, but a large saving might be effected in the printer's bill, sufficient, no doubt, to provide ample remuneration for the sub-editor. In these days of technical education there would be little difficulty in finding a young man perfectly qualified to fill such a post. Cases of doubt, when they arose, might be referred to the secretary or the editing committee (if it still exists), who would, of course, be ultimately responsible.

It might be urged that the proposed plan could not be carried into effect without the risk of giving offence to individuals, and wounding susceptibilities. To some extent this would perhaps be unavoidable, especially in the earlier days of the reform; but any objection arising from such a cause would be far more than outweighed by the gratitude of those whose duty it is to

Digitized by Google

read the *Journal* on having their present wearisome task lightened, and by the disappearance of all real ground for that suspicion of contempt and ridicule with which there is at present an undoubted tendency to regard our proceedings.—Yours, &c.

SHELFORD BIDWELL, F.R.S., M.Inst.E.E.

January 14th, 1889.

MR. EDMUNDS' METHOD OF MAINTAINING CONSTANT CURRENT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the course of his Paper on "A System of Electrical Distribution," read before the Society of Telegraph-Engineers and Electricians on the 22nd November last, Mr. Edmunds made a statement that no governor was required on his steam engine, which automatically increased its speed as the work was put on, and, *vice versâ*, slowed up on the work being taken off. Evidently others besides myself were a little in the dark as to how this was possible, for Mr. W. H. Preece asked for an explanation. Mr. Gisbert Kapp, who followed, opened his remarks by saying that "Mr. Bernstein" had "already done it," and "it is a perfectly easily understood thing . . ." "The pressure against the piston being constant, the torque on the armature is constant; and as the field is also constant, the current must be constant . . ."

As I was unable to accept this as an explanation, I subsequently rose, and, in the course of other remarks, asked for further information.

Being unable to attend the next meeting of the Society, I turned to your columns of the 21st ult., but was much disappointed to find that, beyond saying practically it is easy if you only know the way, Mr. Edmunds had ignored the remarks of Mr. Preece and myself, and I therefore awaited the publication of the *Journal* of the Society to see if I had misapprehended the conditions, and was almost surprised to find that such was not the case.

These conditions are that a boiler with constant pressure maintained in it drives an engine without a governor, and between itself and which nothing is inserted except the ordinary starting and stopping valve. This engine with the boiler pressure acting "direct on to the piston"—drives a separately excited dynamo, and as long as these conditions are observed speeds up as work is put on, so that a constant current is always maintained in an external circuit whose resistance varies from short-circuit to an unstated amount, say, such that 2,000 volts are required to do it; or, in other words, and taking Mr. Edmunds' own statement of current, 70 amperes. The engine, the starting valve of which has been opened so that it drives the dynamo just fast enough to generate 70 amperes at, say, 10 volts (= 700 watts, say, one brake-horse-power), will, without attention to anything except the maintenance of a constant steam pressure of 70lb. on the boiler, and without alteration to the starting valve, *increase* its speed until it gives 70 amperes at 2,000 volts = 140,000 watts, or, say, 200 brake-horse-power.

If the pressure of steam acting on the area of the piston is just sufficient to drive that piston so many feet per minute, how is it that the same pressure is capable of driving the same piston at double or treble the speed with the same resistance per turn to overcome, *i.e.*, do the same work in half or one-third the time?

Why is it necessary to use a separately-excited dynamo? If the current be constant, are not the watts lost in the fields of a series machine constant also?

Finally, if the adoption of a constant boiler pressure and a separately excited dynamo is all that is necessary to ensure a constant current, why trouble about elaborate engine governors as Willans', Richardson's, and others, or dynamo regulators as Thomson-Houston's? Why spend large sums on big engines when all that is necessary is to get one capable, with a certain boiler pressure, of driving a dynamo which gives some 50 volts and 10 amperes? An arc lamp can be driven at that speed. Two, ten, twenty arcs only require additional speed, for "equal current electromotive force is very nearly exactly proportional to the velocity of rotation," says Dr. S. P. Thompson in his "Dynamo Electric Machinery." The work per turn is the same, and within the limits of speed to which the engine can be worked without flying to pieces, two, ten, twenty horse-power can be got out of a one-horse engine.—Yours, &c.,

DOUGLAS C. BATE.

STANDARDS OF LIGHT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your editorial remark that "I am a firm adherent of the venerable wax candle, and stoutly maintained at the Society of Arts that it was all the most enlightened could desire, &c.," I take to be banter—at all events, it is an amusing misrepresentation. As a fact, I advocated the Amyl Acetate Lamp of V. Hefner-Alteneck, which I had the honour to bring to the notice of the authorities some four years ago through the courtesy of Messrs. Siemens. The experiments I then made led me to express a high opinion as to the steadiness of this unit, and the official trials since made have amply confirmed my results. With some minor changes I believe this lamp can be adapted to serve as a standard of light accurate enough for all practical purposes.

Most of your readers cannot ascertain what I said on the "Standard Candles," and if I remain silent might take your remarks seriously. May I, therefore, say that I quite agree with Mr. Vernon Harcourt and every other authority in condemning the present sperm candle, but I further agree in his forecast that it is likely to remain the Parliamentary standard for some time to come. Now, I contend that while we have to use sperm candles every care should be taken to ensure the minimum variability, and the question is whether more uniform candles cannot be supplied.

At present any candles running six to the pound and professing to be of sperm, made anyhow, by anybody, and with any kind of wick, may be taken as standard candles, provided only they burn anywhere within a 10 per cent. range of 120 grains per hour. I say *professing* to be sperm, although wax is always added to "break the grain" of the spermaceti. Remembering that the demand for these candles is small and their manufacture distributed, can we wonder that they are badly made and very irregular. Obviously they ought to be made at one place, under some control, and with a special view to uniformity.

The serious difficulty is the legal one, seeing that any official control over the manufacture would be illegal, or rather *extra legal*, and might be resented by the interests concerned on the ground that photometric tests would be more stringently interpreted, occasionally, no doubt, to their disadvantage. On the other hand, there are compensatory advantages in a steady unit, and it would be pleasing to hope that representatives of the lighting industries might be appointed to confer with the authorities of the Board of Trade and arrange for the issue of standard candles with some little title to the name. Of course the use of these could not be made compulsory, but there is little reason to doubt they would be eagerly sought for.

I have had a lengthened experience of official photometric testing with the present candles, and I can confidently affirm that I would complain to any chandler who supplied me with the paraffin candles for everyday use that were half as bad and burnt with such fantastically distorted and irregular wicks. I do not wonder at the unsatisfactory results.—Yours, &c.,

M. WHITLEY WILLIAMS.

Ponder's End, London, N., January 15, 1889.

[On referring to the *Journal* of the Society of Arts we find that our correspondent is entitled to complain that the spirit of his remarks was not fairly represented in our note of last week. In fact, Mr. Williams's references to the standard candle were intended to show how to make the best of a "standard" which he agreed with other speakers in condemning as radically faulty. We regret not to have observed this at the first.—ED. *E.*]

BATH ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The tenor of Mr. Massingham's letter affecting my company in your last issue, and the sympathetic comments thereon in the electrical journals being calculated to create the im-

Digitized by Google

pression amongst local authorities throughout the country that they are likely to be denied the benefit of competition in determining to whom they should allot the areas within their jurisdiction, I shall be obliged by your kindly giving the widest publicity to the announcement that the House-to-House Electric Light Supply Company, Limited, whose engineers have hitherto constructed the only central electric lighting stations for the distribution of electricity throughout an extended area by means of underground mains, is prepared to place its experience in both electric light supply and central station construction at the disposal of local authorities everywhere in the United Kingdom.

The House-to-House Company, as its name implies, has no local predilection whatever beyond the usual commercial inducement, and it will be prepared either to apply to the local authorities for permission to apply to the Board of Trade to undertake the business of supply within their areas on its own account or in conjunction with local capital, or to erect for local authorities or independent supply companies central stations on the model of its own at Kensington, which is by general admission the most perfect of its kind.

To this end my company endeavours as far as possible to watch the progress of central station development in all towns in the United Kingdom which, in virtue of their population, present a promising field for the electric light, and its letter to the Bath City Council was prompted by the report of the proceedings of that body, from which it appeared that a contract had been somewhat reluctantly concluded with Mr. Massingham for street lighting only by means of overhead conductors on the faith of representations to the effect that the present position of electrical science did not permit of the work being accomplished by means of underground mains.

Believing, as my directors do, in the advantage to the public of being supplied under the Electric Lighting Act, which not only requires an underground service, but secures rights to the consumer with corresponding obligations on the part of the supplier, they felt that in these circumstances they would be best protecting the interests of the ratepayers of Bath by applying to the Corporation for permission to apply to the Board of Trade to light a limited area of the city for a limited period under a license tenure, and although the unfavourable editorial comments of the electrical journals on their proceedings have been brought to the notice of my directors, they regret to say that they can see no reason to induce them to abandon the step they have taken.

We cannot attempt to justify our ignorance of Mr. Massingham's claims to the consideration of his fellow citizens. All that we knew about him at the date of our letter to the Corporation of Bath was that he was a most respectable boot and shoemaker in that city, and all that we have since learnt on his own admission is, that so far as electricity is concerned, he is "only an enthusiastic admirer of the light of the future."

My directors venture to believe, however, that such qualifications are inadequate for the proper discharge of the responsibility of undertaking "to introduce electricity into several towns of the West of England;" but be this as it may, they trust that if they should follow Mr. Massingham in extending their operations in the future to such places, the electrical press will not in that event bestow its support on him and withhold it from them.—Yours, &c.,

H. St. John Winkworth, Secretary,
House-to-House Electric Light Supply Company (Limited).

117, Bishopsgate-street, London, E.C.

[We have not hitherto thought it necessary to comment upon the proceedings of the House to-House Company in connection with the lighting of Bath; we therefore presume that we are favoured with the above as a circular letter which will make its appearance simultaneously in the columns of our contemporaries. Since, however, our opinion is challenged, we have no hesitation in saying that whilst the House-to-House Company is of course strictly within its legitimate rights in the action which it has taken, yet in the present phase of the electric lighting industry we are strongly of opinion that, especially in provincial towns, competition of this character is greatly to be deprecated. The investment of local capital in schemes such as that initiated and already successfully carried out at Taunton by Mr. Massingham deserves, and should receive, every possible encouragement. Mr. Massingham is understood to have placed himself in the hands of the representatives of one of the best-known systems, and we fail to see any justification for the insinuation that he is not in a position to carry the undertaking to a successful issue. Since, moreover, we consent to the publication of a letter which savours so much of advertisement, we think it necessary to demur to the statement contained in the second paragraph. The central station at Kensington (? West Brompton) may be "the most perfect of its kind," but until we have had an opportunity of visiting it (which we hope shortly to do), we can scarcely be expected to endorse the statement that this is a matter of "general admission."—Ed. *E.*]

THE ALBION GAS ENGINE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your issue for 11th inst. you state that the Albion gas engine gives a nominal horse-power-hour for 13½ cubic feet, and say that no other gas engine can equal this (if verified). I should say not. The most economical gas engine at present in use burns from 20 to 22 feet per indicated horse-power-hour, including side lights, and $\frac{\text{I.H.P.}}{\text{N.H.P.}} = 2$ or $2\frac{1}{2}$, or consumption = 40 to 50 feet per nominal horse-power-hour. Assume the ratio of $\frac{\text{I.H.P.}}{\text{N.H.P.}}$ to be the same in the Albion as other engines, or about 2, this engine gives an indicated horse-power-hour for 6¾ cubic feet per hour. Economy indeed! And taking the actual efficiency of our present engines as 0·14, the efficiency of this = 0·457. Steam is doomed, for the cost of running is less than ⅓rd!

I fear, Mr. Editor, it is too good to be true. Could the makers give us some data from actual tests? No doubt the high speed tends to give a higher efficiency, as also a reduction in weight and cost, but I fail to see (in your engravings) any points of novelty sufficient to account for the efficiency being more than trebled.—Yours, &c., G. T. P.

Govan, January 13, 1889.

THE LIGHTING OF KIMBERLEY—A CORRECTION.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your issue of January 11th I notice that in the account given of the electric lighting at Kimberley the following passage occurs: "The station is also well supplied with ammeters (Slatter's) and voltmeters (Cardew's)."

The "Slatter's" is surely a misprint. We supplied the De Beers Mining Company with instruments made by us under the writer's patent.—Yours, &c.,

J. G. Statter and Co. (Limited).

Alliance Engineering Works, West Drayton, near London,
January 15th, 1889.

THEATRE LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The reply to my protest in your last week's issue from Messrs. Binswanger and Co. is simply evasive. As I have not parted with my own right to manufacture, or determine who shall, the arrangement for theatre lighting and controlling, therefore I have no need to ask for any authority in calling attention to their endeavour to appropriate the arrangement.—Yours, &c., S. Sudworth.

Dorchester and the Telephone.—The Western Counties and South Wales Telephone Company are engaged in a dispute with the authorities of Dorchester which threatens to terminate in the company retiring from the town. The Corporation object to the erection of wires except under their license; the company deny the right of the Corporation to interfere, the wires being carried in all cases at a reasonable height over the streets. If a compromise cannot be arrived at the company intend to withdraw from the borough, rather than enter the law courts.

MESSRS. WOODHOUSE AND RAWSON'S CATALOGUE OF CONTRACTORS' ELECTRICAL SUPPLIES.

The second edition of this well known catalogue has undergone thorough revision and very considerable extension, and now covers 260 pages of closely printed matter, with more than 300 illustrations. We have no hesitation in saying that it is by far the most complete and exhaustive list of electrical supplies which has come under our observation; in fact it would seem scarcely possible that our electric lighting contractors should discover any class of requirement which is not to be found tabulated in these pages. In the chapters on engines and dynamos we find information relating to a large number of machines of both classes, and including gas, water, and petroleum, as well as steam engines, by many of the leading firms, as well as those of Messrs. Woodhouse and Rawson's own manufacture. The incandescent lamps, switches, and holders of this firm have long enjoyed a wide reputation, and are here described in great variety. Amongst the novelties which are catalogued for the first time in this edition we note the following:—Portable plant, search light plant, electric pumps, tramcars and launches, photometrical and wire-testing instruments, the series traction, and telpher systems, &c. All, or nearly all, the more important apparatus supplied by Messrs. Woodhouse and Rawson has at one time or another been described in the columns of *The Electrician*, and we note with pleasure that the descriptive portion of the catalogue is largely made up of extracts from this and other technical journals.

It would be difficult to over estimate the amount of labour and trouble (as well as expense) involved in the preparation of a work of this description, and the way in which it has been carried out reflects the highest credit upon Mr. Rentell, to whom, we understand, Messrs. Woodhouse and Rawson entrusted the work of compilation.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

17,881. J. S. Crowley. Manchester. Improvements in metal arms or brackets for telegraph or telephone posts. December 7, 1888.

17,893. A. McKeand Cochrane. Glasgow. Improvements in *fac-simile* telegraphic apparatus. December 7, 1888.

17,911. A. H. Fletcher and S. W. Cuttriss. Liverpool. Improvements in apparatus for indicating the period electric lamps are caused to burn. December 7, 1888.

17,915. G. R. Gibson and A. F. Macfarlan. Glasgow. Improvements in the insulation of electrical machines and conductors. December 7, 1888.

17,918. F. E. MacMahon. London. Improvements in electrical counting mechanisms. December 7, 1888.

17,927. A. C. Boursot. London. An electric steering indicator. December 7, 1888.

17,929. J. J. Wilkinson. London. Improvements relating to the application of electricity to Turkish, hot air, vapour baths, and the like. December 7, 1888.

17,961. Siemens Brothers and Co. (Limited). London. Improvements in electric generators and motors (A. M. Taylor, India). December 8, 1888.

17,983. H. W. Bishop and F. Brown. Walsall. Improvements in shade-carriers for electric incandescent lamp-holders, affording more rapid means of fixing and unfixing the shades. December 10, 1888.

17,993. A. Serraillier and G. P. Armstrong. London. An improved portable electric lamp. December 10, 1888.

18,018. H. B. Phillips and W. Mitchell. London. Improved electric automatic fire-alarm. December 10, 1888.

18,022. C. E. L. Brown. London. Improvements in dynamo-electric machines. December 10, 1888.

18,035. Sir William Thomson. Glasgow. Improved apparatus for regulating and measuring electric potentials and currents. December 11, 1888.

18,057. P. M. Justice. London. Improvements in cut-out apparatus for electric lamps (C. Heisler, United States). December 11, 1888.

18,091. W. Aldred. London. Improvements in electro-motors. December 11, 1888.

18,108. H. H. Lake. London. Improvements in casings for electric cut-outs (S. Bergman, United States). December 11, 1888.

18,116. A. B. Atkinson and H. Metcalf. Brighton. Improvements in electrical primary batteries. December 12, 1888.

18,137. W. Hartnell. Leeds. Improvements in simple and compound switches for electrical currents. December 12, 1888.

18,154. P. C. Wood. London. Improvements in and relating to door-locks and fastenings, consisting of an electro-magnetic lock connected with an alarum. December 12, 1888.

18,187. M. Immisch. London. Improvements in electric generators and in electro motors. December 13, 1888.

18,220. E. Batault. London. Improvements in electricity meters or columb meters (date applied for under section 103 of the Patents, &c., Act, 1883, July 28, 1888, being date of application in Belgium). December 13, 1888.

18,233. H. A. Taylor. London. Improvements relating to duplex electric telegraphs. December 13, 1888.

18,242. R. H. Courtenay. London. Improvements in electrical apparatus for the transmission of sound. December 13, 1888.

18,245. C. Coerper. London. Improvements in electric lamps or lighting apparatus. December 14, 1888.

18,255. N. G. Thompson. London. Improvements in electric alarms. December 14, 1888.

18,262. P. W. Sothmann and C. O. H. Kroll. London. An electric speed regulator for marine engines. December 14, 1888.

18,278. G. Wilkinson and T. W. Holmes. London. Improvements in laying electrical conductors underground. December 14, 1888.

18,306. A. Serraillier, J. T. Armstrong, and The Automatic Electric Supply Company (Limited). London. Improvements in the construction of apparatus for communicating currents of electricity to persons on the introduction of specified coins or checks. December 14 1888.

COMPLETE SPECIFICATIONS ACCEPTED

NOTE.—*All persons interested in opposing the grant of a patent on any one of the undermentioned applications may, at any time within two months from the date in italics, give notice at the Patent Office in the prescribed form of such opposition.*

COMPANIES' MEETINGS & REPORTS.

The Western Counties Telephone Company.

An extraordinary meeting of the shareholders of the Western Counties and South Wales Telephone Company was held at the Grand Hotel, Mr. Charles Nash presiding, on the 9th inst.

The SECRETARY (Mr. H. F. Lewis) read the notice convening the meeting, and the subjoined resolution, which was the cause of the gathering:—

"That Clause or Article 71 of the Articles of Association shall stand as in the original articles, subject only to such variation that in place of the original sub-section (a) the following provision shall be inserted, viz.:—(a) They may borrow any sum or sums of money on such security and terms as to interest or otherwise as they may deem fit, and may secure the same by mortgage or other debentures, or by bonds or other securities, or by any mortgages or charges of or upon the whole or any part of any property, funds, assets, or effects of the company, including its uncalled capital; but so that not more than £50,000 be owing at any time without the consent of a general meeting, and provided that not more than £30,000 shall be borrowed without the consent of the United Telephone Company (Limited), and no borrowed money shall, without the like consent, carry interest at a higher rate than 6 per cent. per annum."

The CHAIRMAN said they would understand from what had been read that the chief object of the gathering was the raising of additional capital. Of the £80,000 which they had power to raise it was only proposed to offer £30,000, and as this would be at the rate of 5, instead of 6 per cent., there would be some saving in interest to the Company. He had to congratulate them upon the steady progress which the system was making. This applied to all their centres. In Bristol, including private line-renters, they had more than 500 subscribers, Plymouth 300, Portsmouth and Bournemouth 200, whilst Torquay, Cardiff, and Swansea, were fast drawing up to 200 each. The Company had recently opened an exchange at Cheltenham, and the prospects there were fairly encouraging. The trunk system had extended, and the contemplated extension between Bristol and Birmingham was in a forward state, and they were looking forward to Bristol being connected with London before the end of the year. That the public appreciated the use of the trunk system was shown by the fact that in 1887 the number of messages spoken was 6,945, and in 1888 14,675—more than double. It was intended to give subscribers the free use of the depôts for local calls, which he thought would have the effect of still further popularising the system. The recent letter in the *Lancet*, written by Mr. A. H. Twining, showing the undoubted accommodation which the telephone was to rural doctors, would doubtless lead many country practitioners to connect their residences with the system. Concluding, the Chairman said although the Act gave them power to raise capital at 6 per cent., yet it was only intended to pay 5 per cent. on the debentures now to be issued. There was nothing further for him to add than to congratulate the shareholders upon the fairly satisfactory condition of the Company.

Mr. MARK WHITWILL seconded the resolution, and said the reason more money was wanted was that the company was compelled to extend its business.

Mr. RICHARD CORY (Cardiff) cordially supported the resolution, and alluded to the immense benefit the telephone was to the coal merchants and others at Cardiff and South Wales, as it enabled them to communicate directly with the collieries. He should not be surprised if the number of messages on the trunk system quadrupled themselves during the ensuing year. There was a great future for the telephone, he felt certain, in South Wales, and this applied doubtless to the other districts in which the Company worked.

The proposal was unanimously adopted, but it will have to be confirmed at a second meeting as a special resolution.

The Direct United States Cable Company (Limited).

Report of the Directors for the six months ended 31st December, 1888, to be presented to the twenty-third ordinary general meeting of the company, to be held at Winchester House, Old Broad Street, London, E.C., on Friday, the 25th inst., at 2 p.m.:—

2. The Revenue for the half-year (still subject to revision on settlement with the French Company), after deducting out-payments, amounted to £34,188. 0s. 0d. against £23,002. 17s. 6d. (after similar deductions) for the corresponding period of 1887, being a difference of £11,185. 2s. 6d. in favour of the half-year under review, owing to the increased tariff in force since the 1st September last.

3. The working and other expenses for the same period, including income tax, amounted to £16,475. 6s. 9d., leaving a balance of £17,712. 13s. 3d. as the net profit of the half-year. For the corresponding half-year of 1887 the working expenses and other payments amounted to £15,864. 18s. 0d.

4. Interim dividends of 2s. per share for the quarter ended 30th September, 1888 (paid 24th October, 1888), and of 3s. 6d. per share for the quarter ended 31st December, 1888 (payable 26th January, 1889), together amounting to £16,695. 5s., have been declared.

5. It having been demonstrated by an exhaustive trial over a period of more than two years that a 6d. tariff did not yield an appreciable profit, the tariff was on the 1st September last raised to 1s. per word, by agreement between the associated companies (including the French Company) and the Commercial Cable Company. The result of the altered rates so far has been to reduce the volume of the traffic, but the receipts have been fairly augmented.

6. The repairs in the deep sea portion of the main cable, to which reference was made in the fifth paragraph of the last report, were completed on the 8th August last, thus placing the cable in efficient working order throughout. The total cost of the repairs, including 218 knots of new cable used, amounting to £58,814. 0s. 1d., has been charged to the reserve fund account. The cost of removing the cables and station from Torbay to Halifax (N.S.) and diverting the cable from Brown's Bank, amounting to £23,638. 10s. 5d., has also been debited to the same account.

7. A joint station (worked by this company) has been established by the Associated Companies at Boston, Massachusetts.

8. Arrangements have been made enabling the company to dispense with the Chester station, which was accordingly closed in December last, whereby a saving will be effected. This station was used solely for transmitting purposes.

9. The appeal of the Cie. Française du Télégraphe de Paris à New York, mentioned in the last report, is still pending.

10. Mr. T. Finnis has been appointed secretary, and Mr. P. Oscar L. Moll traffic manager of the Company, in the place of Mr. J. W. Fuller, who held both offices.

Eastern Telegraph Company (Limited).

The following is the report of the Directors for the half year ended 30th September, 1888, to be presented to the thirty-third half-yearly ordinary general meeting, to be held at Winchester House, 50, Old Broad-street, London, E.C., on Thursday, the 24th inst., at one o'clock :—

2. The revenue for the period amounted to £310,104. 15s. 8d., from which are deducted £83,332. 3s. 0d. for the ordinary expenses and £43,075. 8s. 8d. for expenditure relating to repairs and renewals of cables, &c., during the half year. After providing £4,226. 15s. 7d. for income-tax, there remains a balance of £179,470. 8s. 5d., to which is added £884. 8s. 9d. brought from the preceding half year, making a total available balance of £180,354. 17s. 2d.

3. From this balance there have been paid—

	£	s.	d.
Interest on Debentures and Debenture Stock	£28,264	12	4
Dividend on Preference Shares	20,474	3	10
Two interim dividends of 1¼ per cent. each on Ordinary Shares	95,000	0	0
	£143,738	16	2

Leaving a balance of £36,616. 1s., which is carried forward to the next account.

4. The revenue includes £25,791. 15s. 11d. dividend for the half year upon the Company's shares in the Eastern and South African, the Black Sea, and the Direct Spanish Telegraph Companies. The cables of these companies are in good working order.

5. Details are given in Abstract C of the accounts of the repairs and renewals of the cables, the several sections of which are now in good working order, with the exception of the Aden-Bombay original cable, which is under repair.

6. The Directors have entered into a new convention with the French Government for the special wire through France, in connection with the Company's cables at Marseilles, and the prolonged negotiations on this subject are thus satisfactorily concluded.

7. In accordance with the special resolutions passed at the extraordinary general meeting held on the 22nd November last the 20,000 new ordinary shares have been issued and taken up by the shareholders at £12 per share.

8. The new cables for the West Coast Lines of the Eastern and South African Company, which are to be worked by this Company, are in course of manufacture by the Telegraph Construction and Maintenance Company, and the India Rubber, Gutta Percha and Telegraph Works Company, and will be laid, according to contract, during the spring.

9. The Directors regret to announce the death, in August last, of Lord Alfred Paget. The vacancy thus occasioned on the Board has been filled up by the election of Sir Albert J. Leppoc Cappel, K.C.I.E., late Director-General of Telegraphs in India.

10. In accordance with the Articles of Association, two of the Directors, Lord Sackville A. Cecil and Sir Albert J. Leppoc Cappel, retire by rotation at this meeting, and being eligible offer themselves for re-election.

11. The auditor, Mr. Henry Dever, retires and offers himself for re-election. The auditors, Messrs. Quilter, Welton and Co, also retire, and offer themselves for re-election under their new style of Welton, Jones and Co., adopted since the death of Mr. Quilter.

THE EQUITABLE TELEPHONE ASSOCIATION (LIMITED).

The following circular letter has been issued to their customers by the Equitable Telephone Association :—

75, Queen Victoria-street, London, E.C.,
27th December, 1888.

SIR : You are, we believe, aware that the United Telephone Company, some months ago, commenced an action against the Association for infringement of their telephone patents, and that they obtained an interim injunction pending the trial of the action.

The shareholders of the Association, in general meeting, having decided not to provide further funds to continue the litigation, the Association is consequently unable to further contest the question of infringement raised by the United Telephone Company, and, having regard to all the circumstances of the case, have found no course open to them but to submit to a perpetual injunction on the usual terms. At the same time, the United Telephone Company have undertaken not to make any claim for damages against persons who have purchased or have been supplied with telephone instruments by the Association for their own use, provided they deliver up such instruments intact to the United Company, of Oxford-court, Cannon-street, E.C., by the 4th January.

The Equitable Telephone Association in these circumstances regret that they can only suggest that customers of the Association shall give up their instruments to the United Company accordingly, and by so doing avoid possible liability.

The Equitable Telephone Association having no further funds, and the injunction practically putting an end to their business, will now be obliged to wind up its affairs.

For the Equitable Telephone Association (Limited).

CHAS. J. WARDEN, Secretary.

NEW COMPANIES REGISTERED.

NEWCASTLE-UPON-TYNE ELECTRIC SUPPLY COMPANY (LIMITED).—This company was registered on the 8th inst., with a capital of £50,000 in £5 shares, to supply electricity for lighting and other purposes in Newcastle-on-Tyne, and elsewhere in the counties of Northumberland and Durham. The number of directors is not to be less than 3, nor more than 9 ; the subscribers are to appoint the first ; qualification £100 in shares or stock ; the company in general meeting will determine remuneration.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this company for the week ended January 11th amounted to £5,247.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—The board of this company have resolved upon the payment of an interim dividend of 3s. 6d. per share, free of income-tax, being at the rate of of 3½ per cent. per annum, for the quarter ended December, 1888, such dividend to be payable on and after the 26th inst.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—This company notifies that the interest, due on February 1 proximo, on their Six per Cent. Debentures will be paid on and after that date at the Consolidated Bank, 52, Threadneedle-street, E.C. Coupons must be left three clear days for examination.

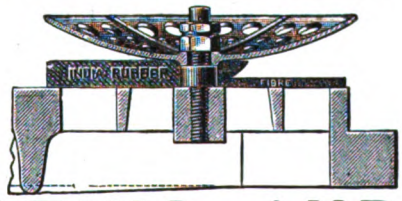
GLOBE TELEGRAPH AND TRUST COMPANY.—The directors of this company have declared a dividend for the past quarter of 3s. on the preference and 1s. 3d. on the ordinary shares.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this company for the week ended January 11, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,248.

REMOVAL.—Mr. A. A. Campbell Swinton has opened new offices at 66, Victoria-street, Westminster, where all communications should now be addressed to him.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.
"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 558.—Vol. XXII. FRIDAY, JANUARY 25, 1889. Price Sixpence.

NOTES.

We this week have the pleasure of presenting to the subscribers of *The Electrician* a steel plate portrait of the new President of the Institution of Electrical Engineers, Sir William Thomson, F.R.S., &c., &c. The portrait has been engraved from a photograph taken by Elliott and Fry, of Baker-street, by means of the electric light.

We understand that a committee of the Council of the Institution of Electrical Engineers has been formed to consider, in conjunction with the Board of Trade, the regulations for controlling overhead wires. This committee has been appointed at the request of the Board of Trade.

Prof. Forbes' interesting Paper on "Electricity Meters," read before the Society of Arts on Wednesday evening, derives additional importance from the fact of its being really the first occasion on which a connected view of the subject has been presented. Prof. Forbes laid down no less than fifteen points as essential to the perfection of a meter, and he described in detail some six or eight instruments which come within measurable distance of that standard. We used to be told that the proper thing to do was to measure the watts, and that coulomb-meters were to be considered merely as makeshifts; Prof. Forbes, however, maintains that it is better to integrate the current only, and trust to the inspectors to look after the volts. Prof. Ayrton objected to this strongly, chiefly on the ground that a very small variation of voltage—a variation within the allowed limits—makes so great a difference in the light actually supplied. Moreover, if you are charged by coulomb-meter, and you turn on additional lamps because the volts have fallen off, you have to pay for the additional current. To this Prof. Forbes retorted that if you are charged by erg-meter, and the Company chooses to overrun your lamps, not only have you to pay for more light than you want, but you have also the pleasure of buying an additional number of lamps per annum. However, the public may take it for granted that these little difficulties are not really so formidable as they appear, and in comparison with the iniquities of gas-meters the electricity meter may almost be pronounced immaculate. Next week we hope to print the Paper in full, together with a report of the debate.

Prof. Jamieson has also done good service in bringing the subject of the Insulation Resistances of Installations before the Institution of Electrical Engineers. It is to be feared that the practice of testing insulation resistance has been very much neglected in the electric-lighting industry; but Prof. Jamieson's hints for the use of ordinary ammeters and voltmeters for this purpose will, no doubt, be of assistance to many people. It is very satisfactory to find that Prof. Jamieson's experience leads him to believe that there is no practical difficulty in an average case in attaining an even higher standard of insulation than that demanded by the Installation Rules of the Institution.

The Council of the Institution of Electrical Engineers, after mature deliberation, has arrived at the conclusion that the welfare and the dignity of the Institution will be best consulted by the exclusion of newspaper reporters from its debates. The question is one of greater importance to the Institution than to the technical press, and for our own part we do not pretend to have given it that thorough consideration which would enable us to arrive at any very decided opinion. In our issue of December 11th we committed ourselves to the observation that much might be said on both sides of the question. It is, for instance, clear on the one hand that any tendency on the part of members to abuse the facilities offered by the Institution in order to advance their individual schemes with the outside public should be strongly discountenanced. On the other hand, we must confess that we were not previously alive to the fact that such a state of things existed to anything like a serious extent. It is also obvious, from the same point of view, that the non-reporting of the debates entails additional responsibility upon the Council in respect of the Papers accepted, and it would perhaps have been a more consistent course had their publication likewise been discontinued. Any movement which conduces to the best interests of the electrical engineering profession must necessarily command our cordial assent, and in these matters the Council of the Institution ought certainly to be the best judges—only we would have them bear in mind that the Institution exists for the sake of electrical engineering, and not electrical engineering for the sake of the Institution.

On most of the points raised in Mr. Shelford Bidwell's letter, which we printed last week, we are inclined to agree with him. But after giving the matter some further consideration we still think he has left the main point in dispute pretty much where it was. At bottom the demand for an open "house list" of nominations arose out of the objection, which most men entertain, to taking part in an empty formality, especially when that formality consists in registering a foregone

Digitized by Google

conclusion on which they have not been consulted. There are difficulties, no doubt, attending an opposite course; but they are probably not insurmountable; and to overcome administrative difficulties is part of the business of every Council. Mr. BIDWELL does not help them much. In one portion of his letter, if we understand him rightly, he states that when the ballot paper reaches him with more names than have to be elected he flings it into the waste paper basket, because in his judgment, the Council ought to have saved him the trouble of selection. We should like to ask him what he did with the paper when it nominated those only who were to be elected? Did he return it? If so, with what object? The gist of the whole matter is contained in this last question; and we should be glad to hear from anyone who has a rational answer to give to it.

MR. CAMPBELL-SWINTON gives in this issue an interesting account of the investigation carried out by Mr. W. BROWN (of the Central Telegraph Office) on the cause of the interference on the Equitable Telephone Company's wire in Knightrider-street. After Mr. PREECE'S more extended experiments upon the same subject we do not, however, know that we are called upon to express any great degree of surprise that the telephone should prove sensitive to disturbances originating at a distance of 100 yards. There is, however, one distinguishing feature in this case which deserves greater attention than it has received, and which, moreover, affords a beautiful illustration of Dr. FLEMING'S "Theory of Screening," which we published last week (see *The Electrician*, January 18, p. 300). We refer to the fact that the wire which influenced the telephone was enclosed in an iron pipe.

IN our issue of June 22nd, 1888, we recorded the result of a test case which had been brought before the United States Circuit Court with the object of determining the validity of a whole batch of the Edison patents, including a sweeping claim to the use of incandescent lamps in multiple arc, and also several of the most important patents for the manufacture of lamps. These claims were all open to the objection that the life of the analogous patents in one or more foreign countries had already terminated, and it was maintained that in accordance with the United States Patent Law the American patents had lapsed at the same moment. This interpretation was upheld by the lower Court, but we learn from a telegram in the *Standard* that this decision has been reversed, on the ground that the United States patent extends "to any period to which the foreign patent may be extended, and that irrespective of whether the privilege of the extension abroad is exercised or not." This decision would appear to be of the utmost importance to the electric lighting industry in the States, and we await with interest the arrival of definite information from our New York correspondent.

SINCE writing the above we have received the following cablegram from our New York Correspondent :—

"The United States Supreme Court, Washington, rendered on Monday last, in the case of the "Bate Refrigerating Company *v.* Hamond and Co.," a very important decision, bearing directly on electric lighting interests. The decision was to the effect that, contrary to opinion of Circuit Court below, an American patent was not limited in its duration by the shorter term of the foreign patent, but should run its full course, unaffected by original term of patents taken out abroad and afterwards extended. This affects favourably about a dozen of Edison's leading incandescent lamp patents, which had been taken out abroad originally for shortest term permitted. The Bate case, in the Supreme Court, has been carried on with help of the Edison counsel. The way is now cleared for direct adjudication on merits of patents, and it is said that suits proper will be actively taken up at this juncture. It is interesting to note that the parent Westinghouse and United States Electric Lighting Companies have just entered into working arrangement on both a patent and manufacturing basis. It is a strong combination."

WE understand that Captain CARDEW, R.E., has been appointed Technical Adviser to the Board of Trade in connection with the Electric Lighting Acts. We may add that the Board of Trade has adopted the recommendation of the London Chamber of Commerce in the matter of the unit of electrical supply, which is now defined as the equivalent of 10,000 amperes flowing under an E.M.F. of one volt during one hour.

WE have the highest authority for the statement that it is impossible for any man to serve two masters, but it is the unhappy fate of the Electricity Supply Companies to attempt the still more hopelessly impossible task of serving not merely two, but a whole multitude of masters. First and foremost, they have to please the public, and this is probably the easiest part of their duty. Then there is the "local authority" to be considered, which—not to put too fine a point upon it—is apt sometimes to be pig-headed. Next there is the all-powerful and irresponsible authority embodied in the redoubtable Mr. HEAPHY, Inspector-General of Fire Offices. Lastly, but not least, the edicts of the Board of Trade, representing Imperial power, have to be received with due submission. Now, supposing—we only say supposing—that between these two last-named and most potent masters an irreconcilable conflict of opinion should arise, what on earth are the companies to do then, poor things? Supposing, for instance—and our readers will not fail to note that we only say supposing—the Board of Trade in the performance of their important duties were to become convinced that the public safety demanded the use of a certain specified device to avoid the danger of the primary current entering the secondary circuit of a transformer, and supposing that the Fire Offices arrived at a diametrically opposite conclusion, what then would be the position of the Electricity Supply Companies, and what would be the position of the electric light? These are questions which we confess our total inability to answer, but (though we only said "supposing") it is, perhaps, of some consequence to look them in the face.

WE are informed that the contract for the construction of the Southwark Bridge station of the Metropolitan Electric Supply Company has been awarded to Messrs. JOHNSON and

Digitized by Google

PHILLIPS, who will employ the alternating-current system of Mr. GISBERT KAPP. The plant is to be capable of supplying 500,000 watts at the terminals of the transformers, and will consist of five 120 kilo-watt dynamos, belted direct to separate engines. The boilers will be designed to supply 1,100 horse-power. The tender includes the supply and fitting of every portion of the plant, including engines and boilers, but the steam plant has not yet been finally selected. We may add that the specification requires an alternating current of 16,000 reversals per minute. It is expected that the work will be completed by the end of July.

WE have already made some reference to the Cleveland electric heating hoax, but hitherto we had supposed it to belong to the harmless type of which Cabbage Leaf Filaments recently furnished a successful specimen. (This latter story, by-the-bye, has made its way into *Hardwicke's Science Monthly* as the account of a genuine process.) We learn, however, from the *Progressive Age*, of New York, whose editor evidently implicitly believes in Mr. BREVOORT'S good faith, that a company will shortly be established to work the "new process for the electrical generation of heat." This announcement at once places it in the same category as the Electric Sugar frauds, and it may therefore be as well to denounce the thing as a swindle without more ado.

THE story first made its appearance in the columns of the *Cleveland Press*, and ran to the effect that a mechanic who lived in a back street of that city was on the point of realising an invention no less marvellous than the "generation of heat from electricity."

"For years," he is reported to have said, "I studied and experimented in vain. I commenced on the electro-thermic battery, reasoning that if heat generated the electricity, by working backward heat could be made by electricity. For a long time I clung to this, but had finally to abandon it as practically impossible. Various other theories were tried and many weary hours spent in study when I should have been resting from my day's work. Some of my experiments produced heat, but not in sufficient quantities to be of any benefit." But at length a new light dawned. "The first thing necessary was to form a substance on which the electricity could act. The result of this effort was a composition called carbodium and resembling carbon, of which it is largely composed. By adding certain acids it can be melted and moulded in any form desirable—in masses to put in grates, shaped like radiators, flat, and placed under registers or whatever way wanted. To opposite sides of a piece of this composition wires were connected, and to the opposite ends of one of these an ordinary electric button was attached, on pressing which heat was at once generated in the compositon."

There is a good deal more of this sort of thing, including a pathetic account of the early struggles of the "inventor," and we are told that the current sufficient for one incandescent lamp "will heat with ease almost any number of rooms." The apparatus, which is now on exhibition in Cleveland, is to be rented to subscribers, and will not be sold outright. It is quite unnecessary to say another word to convince the technical reader that the thing is a fraud; but for the sake of the general public we may state that the "generation of heat from electricity" was one of the very earliest discoveries of electricar science, that as to its practical application there is neithel any difficulty nor any mystery about it, though as a general rule it does not pay to carry out. As for "carbodium," nothing could well be more absurd than the addition of acids to carbon to make a fusible compound.

Meiringen.—The little town of Meiringen (Switzerland) will shortly be entirely lighted by electricity.

Metz—The German Government has decided to provide all the forts round Metz with fixed and portable projectors.

Morecambe.—As will be seen by our advertisement columns, the Morecambe Tramways Company invite tenders for working their line by electricity.

The E.P.S. Calendar.—The Electrical Power Storage Company has issued a most useful office requisite in the shape of a combined calendar, diary, address book, and blotting pad.

Rome.—The municipal authorities of Rome have recently appointed a committee to study the question of lighting the entire city by electricity upon the lines laid down by the Anglo-Roman Gas Company and others.

Leeds Mechanics' Institute.—The new wing of the Leeds Mechanics' Institute, which has been built at a total cost of £7,000, was opened on Tuesday, the 15th, by Sir James Kitson, Bart. The new wing comprises the School of Science and Technology and Boys' Modern School.

Mandalay Tramways.—The Municipality of Mandalay have granted a concession to Mr. George E. L. Dawson to construct certain steam or electric tramways in that city. No agreement will, however, be entered into until all the terms thereof have been approved by the committee.

Hooper's Compound.—A piece of an Indo-European cable covered with Hooper's composition, which was laid down in 1868, was recently examined. Though immersed for twenty years it seemed to be in nearly as good a state as when new, the resistance of the insulation being 4,000 megohms per knot at the ordinary temperature.

The Institute of Medical Electricity.—The Institute of Medical Electricity has recently received pleasing testimony to the fact that it is doing good work, in the shape of a present of ten guineas worth of books for the reference library, which a patient has presented as a mark of his gratitude for benefits and attention received at the Institute.

West African Telegraph Company.—The *Gaceta de Madrid* contains a Royal decree from the Spanish Minister for the Colonies, authorising a contract between the Spanish Government and the West African Telegraph Company for the laying of submarine telegraph cables between the Island of Fernando Po and the African coast, and also with Prince's Island.

St. George's (Hanover-square) Vestry.—At a meeting of this Vestry, on Thursday, the 17th, a memorial was read from some ratepayers in New Bond-street, complaining of the annoyance caused by the works of the Grosvenor Electric Lighting Company at the rear of the Grosvenor Gallery. The memorial was referred to committee for consideration and report.

Electric Lighting at Manchester.—At a meeting of the Edison-Swan Company in Manchester, which is further reported in another column, it was resolved to open a central station in Piccadilly for the supply of 10,000 lights, at an average cost of 25s. each. It was stated that the initial expense would be £40,000, and £8,000 per annum would be required to keep the system in operation.

The Cox-Walker Swinton Magneto-Electric Bells.—Mr. A. A. Campbell Swinton, of 66, Victoria-street, S.W., has taken the supply of these instruments into his own hands. Large and powerful bells on this system for use on railways, in mines

Digitized by Google

colleries, &c., are now being made in both tremulous and single-stroke varieties. It is expected that the absence of any battery will render these bells very popular for these purposes.

The Birmingham Electric Lighting Committee.—A meeting of the Sub-Electric Lighting Committee of the City Council was held at the Council House last week. Mr. George Hookham (Messrs. Chamberlain and Hookham) was present, and a discussion lasting upwards of two hours took place on the requirements of the Council with respect to the proposals of the firm named. No decision was arrived at, and the matter was again adjourned.

Holborn Board of Works.—At a meeting last week the Committee of Works reported that they had received applications from the London Electric Supply Corporation and the Metropolitan Electric Supply Company, for the assent of the Board to the company's application for Provisional Orders. The committee further reported that they had directed the clerk to convene a meeting for Monday, February 18th, to consider the applications of the two companies.

Newington Vestry.—At a meeting of this Vestry, on Wednesday last week, the Works and Sanitary Committee recommended—"That the application of the House-to-House Electric Light Supply Company (Limited) for the consent of the Vestry to enable them to apply to the Board of Trade for a Provisional Order be not entertained; but that no objection be offered to the draft Provisional Order lodged with the Board of Trade by the London Electric Supply Corporation, or any action taken to watch the progress of the order through Parliament." The recommendation was adopted.

Exhibition at York.—We have received an advanced copy of the prospectus of the Fine Art, Ecclesiastical, Educational, and Industrial Exhibition to be held at York from June to October next. A part of the cash receipts for admission will be handed to the County Hospital and to the City Dispensary, which, so we are informed, are much in need of pecuniary help. We notice that the grounds are to be "decorated and brilliantly illuminated with *gas* devices," electrical apparatus being relegated to the miscellaneous section amongst aerated waters, preserved food, and other "olla podrida."

The Paris Electric Meter Competition.—A correspondent writes: "For some time I have been looking for an announcement of the particulars of the Electric Meter Competition in Paris, and find a paragraph in your issue this week giving *some* information. Would you please give in your next the date of the competition, the place at which competitors are to enter their names, and such other items as may be useful to competitors." We shall make a point of publishing this information at the earliest possible moment, but up to the present no official announcement has been made beyond what we have already given.

Central Station Lighting in Moscow.—A correspondent writes us from Odessa as follows:—"The Moscow papers state that a few days ago there took place the inauguration of a central electric light station. It is a big edifice of 308 feet in length, 70 feet in breadth, and 160 feet in height. The front is lit by two arc lamps of 2,000 candle-power each. Over 26 miles of underground cables for lighting purposes are laid to the principal parts of the town, and 15,000 incandescent lamps can be supplied. At present there are only 100 trading-houses supplied with the electric light, to the amount of 2,500 16 candle-power incandescents No further particulars have reached here as yet."

Street's "Indian and Colonial Mercantile Directory."—We have received a copy of the new edition of the "Indian and Colonial Mercantile Directory." This work, which is published by Messrs. Street and Co., is of a very useful description. All particulars likely to be of use to commercial men, such as trade, population, steam communication, lists of the principal merchants, &c., are given for the chief trading towns in India, the Colonies, China, and Japan. Maps of all the principal countries referred to, and concise descriptions of each country and town are furnished. The information is well up to date, and this publication ought to prove of great assistance to all engaged in the colonial trade.

The City.—At a recent meeting of the City Commissioners of Sewers Mr. Bridgeman brought up a report of the Streets Committee on the subject of electric lighting, and submitted draft conditions with a view to advertising for tenders. The report was ordered to be printed and circulated, and its consideration adjourned. The Joint Finance and Streets Committee reported, relative to the Electric Lighting Provisional Orders, in respect of which notices have been served upon the Commission, and recommend that the Court do oppose the same for the purpose of obtaining a *locus standi*, that it be referred back to them to watch and report thereon from time to time as may be necessary, and the clerk be authorised, on behalf of the Commission, to sign the necessary objections to be submitted to the Board of Trade.

The Liverpool Electric Supply Company.—The Watch Committee have resolved, after considering a report of the city engineer on an application of the Liverpool Electric Supply Company for the consent of the Corporation to their applying for a Provisional Order, that the Town Clerk reply that, having regard to the short time which has elapsed since the grant of the license, the committee have not had sufficient opportunity of observing the working of the system to enable them to adequately consider the application, and they therefore cannot recommend the Council, as the local authority under the Electric Lighting Acts 1882 and 1888, to consent to the company making an application for a Provisional Order.—The Health Committee have approved of a report of the City Engineer on plans submitted by the above company showing the position in which they propose to lay mains in the streets.

Reading.—It will be remembered that some two or three months ago Messrs. Laing, Wharton and Down obtained the sanction of the Reading Town Council to erect some arc lights in the main thoroughfares. That the firm are confident of doing business in the town is shown by the fact that they are putting down a costly and permanent plant on a site on what is known as the "Island," which has been acquired by them. In the boiler-shed provision has been made for two 25-horse power boilers, one of which is already *in situ*. Twin Armington-Sims engines of 9 horse-power nominal have been laid down to drive the dynamos. The dynamos (also in duplicate) are of the Thomson-Houston type, and these are each capable of running twenty 1,200 candle-power arc lamps. Thomson-Houston lamps will be employed for indoor purposes, and Thomson-Rice lamps for outdoor use. It is said that many of the business firms in Reading contemplate adopting the light.

Barnet.—At the meeting of the Barnet Local Board on Tuesday in last week, Mr. James asked whether any reason had been given for the failure of the electric light on the previous Friday evening. The lamps, he explained, were not exactly out, but they were like "red bars of iron, giving no light." The surveyor, in reply to the chairman, said he was unable to give any information. He had no instructions from the Board; no lighting inspector had been appointed, and he did not wish to volunteer a report. The chairman said it had occurred to him that they ought to have someone who really understood the matter, and who could give an independent and authoritative opinion whether the lamps were up to 32-candle-power, as provided for in the contract. They had no means of settling it for themselves; and they wanted the opinion of an expert who could swear to what he stated. A long discussion ensued, and in the end it was agreed to appoint an expert to report upon the whole subject of the electric lighting of the district. Another breakdown occurred on Wednesday evening, the light not being available up to a late hour.

The Jubilee of Electroplating.—It is now a little more than half a century ago that Jacobi, the originator of the first attempts at electrical navigation, published his discovery of the art of electroplating. In October, 1838, at a meeting of the Académie Impériale des Sciences, Jacobi imparted the results of his investigations to his colleagues, and in December of the same year the great discovery was announced in the papers. The Société Impériale Technique, at the instance of its secre-

Digitized by Google

tary, M. Sreznevsky, has decided to celebrate this important anniversary by an exhibition, which will open in the middle of next month, and which will be divided into the following sections: 1. The history of the discovery of electroplating, including several specimens of Jacobi's first attempts and his correspondence upon the subject with various scientific bodies. 2. The technology of electroplating, with examples of its application to electrometallurgy and chemical analysis. 3. The application of electroplating to the arts and to industry. The Société Impériale Technique will celebrate the event by a *séance*, at which the President, M. Chwolson, will give an address on the significance of Jacobi's discovery.

The Dundee Art Galleries and the Electric Light.—A meeting of the Building Committee of the Victoria Art Galleries, Dundee, was held last week for the purpose of considering a report as to the best means of lighting the new galleries and the whole Albert Institute with the electric light. The report was drawn up by Mr. W. A. Bryson. Treating the Albert Institute as a whole—museum, picture gallery, both libraries, and the new galleries—Mr. Bryson proposed a very complete scheme, embracing arc lamps for the larger galleries and halls, and incandescent lamps for the smaller rooms, the initial cost of which, including everything—engines, dynamos, wires, lamps, &c.—would amount to £2,800, the annual working expenses to £180, and the annual cost of plant, including depreciation, to £443, or altogether £623 per annum, all these, however, being very full estimates, more likely to be lessened than exceeded. It was stated that the cost of gas for a year for the whole Albert Institute, including the amount consumed in the new galleries during the three or four months of an annual exhibition, would be fully £300. After discussion the question was remitted to a special sub-committee to obtain skilled professional opinion and report to a future meeting.

St. James's Vestry.—At a meeting of this Vestry on Wednesday, 16th inst., assent was given to the introduction of the Metropolitan Electric Supply Company's Bill to authorise the company to supply electricity in the parishes of St. James's (Westminster) and St. Martin's-in-the-Fields, on the terms and conditions agreed to last year. It was decided to offer no opposition to the draft Provisional Order of the London Electric Supply Corporation, on condition of certain amendments being made in the same. The amendments proposed were of a stringent character, and included the company undertaking to satisfy the Board of Trade that they were in a position to carry out obligations before beginning operations; not to associate themselves with any other company without the consent of the Vestry; and to remove all overhead wires, supports, &c., on notices to that effect from the Vestry, under penalty; and that the plans for the generating station and proposed buildings should be submitted to and approved by the London County Council. The Lighting Committee recommended:—"That the Board of Trade be invited to specially consider the proposal of the London Electric Supply Corporation to take powers to lay trunk mains in the district without coming under any obligation to supply electricity therefrom in such district, and also the proposal of the Corporation to take powers to supply electricity to local authorities for the latter to retail to consumers." The recommendation was adopted.

Address to Sir John Pender by the Glasgow Telegraph Staff.—The following address, which was signed by a majority of the leading officers and a large portion of the telegraph staff in connection with the Glasgow Post Office was forwarded to Sir John Pender on Saturday last:—"Sir: We, the undersigned members of the Glasgow Postal Telegraph staff, consider your presence in our city a fitting opportunity for expressing to you our appreciation of your efforts and success in establishing and extending telegraph communication all over the world. Thereby a great and valuable outlet is afforded for the employment of telegraphists, also mechanics and other workmen—an outlet which to telegraphists especially has been of the greatest value. In consequence of the liberal manner in which telegraphists in the employment of the companies are treated clerks are continually being induced to transfer their services from the Post Office to the service of the companies, and thereby the congestion of promotion in the Post Office is to some extent relieved. The considerations are to some degree sectional and local, and while the beneficial results of your enterprise have not been confined to us or to any class, but have extended to the whole commercial and industrial interests of Great Britain, we desire to place on record your generosity to your servants as a matter of our immediate and personal knowledge, and as a simple testimony of your symyathy with the workers of the world."

Chelsea.—The Electric Light Committee of the Chelsea Vestry reported at their last meeting that they had considered the copy of a deposited map and advertisement of application for Provisional Order by the London Electric Supply Corporation, Limited; also the letter from Messrs. Deacon, Gibson and Medcalf, on behalf of the London Electric Supply Corporation, Limited, notifying that they have deposited at the Board of Trade the draft of the Provisional Order for which they are making application, and enclosing a copy of the same; also asking for the Vestry's assent to the granting of the Provisional Order, and stating that they will be happy to afford all such further information as may be desired, and that they will, at the commencement of February, have to report to the Board of Trade whether the Vestry assent to the application. The Committee recommended that the Vestry do dissent from the granting of the proposed Provisional Order. The report was adopted. The Committee also reported that they had considered the memorial, bearing 432 signatures, presented to the Vestry on the 18th ult., praying for the removal of overhead wires, wherever the Vestry has jurisdiction, and recommended that the Vestry inform the memoralists that the jurisdiction of the Vestry in the matter of overhead wires is limited in extent, difficult of application, and doubtful in its effects, and that the Vestry are not prepared at present to initiate litigation against the owners of overhead wires. The report was adopted.

Electric Lighting at Portsmouth Dockyard.—We make the following extract from a leading article in the *United Service Gazette* of January 19th:—"Electric lighting has made, and is making, great strides at Portsmouth Dockyard. Mr. Lane, the electrician, commenced the work in the early days of naval search lights with a man and a boy. Now the electrical shop employs ninety-six hands, the greater number of whom are fitters, and within the next three months it is expected that this number will be increased to 250 hands, as the department is about to undertake the manufacture of the electrical apparatus fitted in Her Majesty's ships to a far greater extent than it has done in the past. Electricity has, no doubt, a great future before it, and it is satisfactory to learn that the Admiralty are beginning to move with the times with regard to this important branch of science. Electricity, for lighting purposes, is invaluable when ships are in course of construction and of being fitted. Under the ships' bottoms and in the interior of the ships, especially in the double bottoms and the other lower depths, the work has been expedited and improved, and inspection has been rendered far more speedy and much more effectual by the use of the incandescent light. A man can take a coil of wire and a 16-candle power light, and with it light up the darkest corner of the ship as it could not have been lit with the old system of matches and candles, which did little more than make darkness visible, to say nothing of the danger of fire; while the "stink-pots," which of old were supposed to light under the bottoms of ships were simply abominations. The difference between muddling along with shipbuilding work in semi-darkness and working under the brilliant illumination of electricity is so vast that officers and men are apt to wonder how they managed before they got the electric light. With regard to search lights, all the electricians have to do is to provide them. Their utility in action—that is, when they should be used and when they should not be used—still, we venture to think, requires great consideration and much experiment on the part of executive naval officers. The legitimate use is, no doubt, to show up advancing torpedo boats, and thus enable the quick-firing guns to play upon them; but, on the other hand, when within range of an enemy's artillery, the fact of using search-lights shows your position very accurately to their gunners.

SIR WILLIAM THOMSON.

We publish this week a portrait of Sir William Thomson, recently (and for the second time) elected President of the Institution of Electrical-Engineers.

Sir William Thomson, though of Scotch descent, is an Irishman by birth. He was born in Belfast in June, 1824. For several generations his family had occupied a farm near Ballynahinch, in the County of Down; but his father, Dr. James Thomson, a very remarkable man and a born mathematician, managed to secure for himself an education at Glasgow University (travelling was not so easy in those days as it is now, and colleges were not so plentiful), and subsequently he became Professor of Mathematics at the Royal Belfast Academical Institution, and at a later date in the University of Glasgow itself. It was while Dr. James Thomson was Professor in Belfast that William Thomson was born, and he was eight years of age when his father removed to the old College in the High-street, Glasgow.

The children of Dr. James Thomson were educated by himself so long as they were children; and they seem to have early imbibed a taste for learning of every kind and much sound knowledge of the most diversified nature. At a very early age William Thomson and his elder brother, James (now Professor of Civil Engineering), were at Glasgow College together, and both are well remembered by those who were their class fellows. William Thomson was specially remarkable—an enthusiastic, eager little lad of twelve—jumping up to answer *viva voce* questions, when his chief difficulty was to make himself seen among his older class fellows.

From Glasgow William Thomson went to St. Peter's College, Cambridge, and in 1845 he graduated as Second Wrangler and first Smith's Prizeman; and he was elected a Fellow of his College. At Cambridge his main work was, it is needless to say, mathematical; but his tastes were by no means confined to this subject of his choice. Literature of all sorts and music had great attractions for him; and athletics were not neglected. He was President of the Cambridge University Musical Society for a time; and he won the Colquhoun Silver Sculls the first time they were rowed for at Cambridge. Anything 'with water in it' has a fascination for him—swimming, rowing, sailing, steaming, the Atlantic waves, his own Netherhall burn, the "rivulet down Trumpington-street," the capillary ripples made by a fishing line which is moved through a placid sea.

Even before his Glasgow student days came to an end we find Sir William Thomson's original work in science had commenced; and his first mathematical Papers, written before he entered Cambridge as an undergraduate, are well worthy of attention. They were both connected with the Fourier Mathematics, then but little known; and these early studies have probably given a colour to much of his subsequent work. In a Paper which was published in 1842, in the Cambridge and Dublin *Mathematical Journal*, on "The Uniform Motion of Heat in Homogeneous Solid Bodies, and its connection with the Mathematical Theory of Electricity"—written at the age of seventeen he points out the analogy between certain problems in conduction of heat and in the mathematical theory of electricity and magnetism; and he shows how to make use of solutions of the one set of problems in order to establish important conclusions with regard to the other class of questions.

The Papers just mentioned were followed by a Paper on "Linear Motion of Heat," which contained principles which he subsequently so powerfully applied to the question of "Geological Time." This was also published in 1842, and in 1845 he communicated to Liouville's *Journal de Mathématiques* a Paper on the "Elementary Laws of Statical Electricity." In October, 1845, and in June, 1846, he contributed to the same journal a letter addressed to Liouville, and an elaborate Paper on his principle of "Electric Images," a subject on which he seems to have spoken to the veteran mathematician during his residence in Paris about that time.

It is impossible, within the limits of the present notice, to discuss, or even to mention, the many Papers which flowed from the pen of Thomson about this time; but two somewhat general remarks which will be interesting to electricians may be made with respect to them. In the first place, the years about which we speak just now were of high interest and importance in the history of electric and magnetic science. The discoveries of Faraday in electrostatics and magnetism, and the ideas introduced by him, had given a new mode of thinking of some of these subjects. The function of the dielectric had been recently discovered and traced out, and the doctrine of lines of force had been expounded. Henceforward, action at a distance, so far as electricity and magnetism were concerned, was, so to speak, a notion of the past—an hypothesis utterly untenable and incapable of representing the facts of the case. Thomson early grasped this truth; and making the new knowledge the basis of his mathematical investigations, gave to its expression a mathematical form which endued it with fresh power.

The second general remark that we would make is this. At the age of seventeen Thomson, as we have seen, devoted himself to the study of attraction, and in his earliest Papers gave a large number of important general theories connected with this subject. The results of these investigations were very soon translated into the language of "the potential;" and the connection was established between these results and the theories connected with the science of energy which was coming into prominence through the labours of Joule. Thus it was that Thomson, at the age of twenty-one, became the exponent of doctrines, the full value of which can scarcely be said to have been appreciated before he was double that age. In 1867, or about that time, the word "potential," now so familiar to students and the merest beginners in electrical science, was unknown, except to a few mathematicians of the more advanced type. Can the Society of Telegraph-Engineers picture to itself the benighted condition of an electrical world like that?

In 1846 Thomson was elected Professor of Natural Philosophy in the University of Glasgow; and thus at twenty-two he was appointed to the chair which he has filled with such distinction and continues to hold. More than one offer has been made to him, the most tempting of which have been offers from the English University for which he entertains so affectionate a regard; but he has preferred to remain in his northern professorship, and his constancy is appreciated by the University which he adorns.

The dynamical theory of heat early engaged the attention of Sir William Thomson. His Papers on this subject were communicated to the Royal Society of Edinburgh. The first of these was published in 1849. Thomson was among the first to appreciate the importance of the work of Joule; and his earliest Paper on thermo-dynamics is occupied with a critical study of Carnot's "Réflexions sur la Puissance Motrice du Feu," published in 1824, and shows how the theory of Carnot may be altered so as to correspond with the modern doctrine regarding the nature of heat. His series of Papers on the subject of thermo-dynamics just mentioned form one of the most valuable and most remarkable of all the contributions with which Sir William Thomson has enriched physical science. The principle of dissipation of energy was announced in 1852; and in connection with these mathematical researches experimental determinations were undertaken by Joule and Thomson, and more than one joint Paper of high value was contributed to science by these two life-long friends.

In 1855 was published Sir William Thomson's Paper on "Electro-Dynamic Qualities of Metals." It was given to the Royal Society, and was made the Bakerian Lecture for the year. It was while he was engaged in experimental work in connection with this research that Sir William Thomson began to make use of the assistance of his students; and this was the commencement of the Physical Laboratory of the University of Glasgow, which was in fact the first of Physical Laboratories.

The Bakerian Lecture has been followed from time to time by Papers on the same subject, and the lecture itself and its continuations have proved a veritable nursery garden from which healthy seedlings have been transplanted in all directions—in Scotland, to England and Germany, and even to far Japan. And, being nurtured and carefully tended, these have grown into goodly plants, greatly to the honour and glory of their cultivators.

In 1855 and 1856 a new field opened itself to the genius of Thomson. The problem of ocean telegraphy had presented itself to the world, and very soon he was practically called upon to solve it. To give a complete history of this time, interesting as it is to electricians, is beyond our present limits. A brief sketch must suffice.

Following up the 1854 experiments of Faraday, Thomson had investigated mathematically the subject of *the retardation of signals*, and had given the *law of squares*, now so familiar to all telegraphers. When the possibility of laying down an Atlantic cable came to be discussed, it therefore became evident that a cable of such a length as 2,000 miles, unless of unprecedentedly large transverse dimensions, might prove a commercial failure on account of the slowness of the transmission of signals through it. Mr. Whitehouse, however, at the Cheltenham Meeting of the British Association (1856), endeavoured to disprove the law, and to show that much more speedy transmission of signals might, than according to it, be expected.

In September and October, 1856, we find Thomson answering the statements of Whitehouse in two letters to the *Athenæum*. These letters, if there were space at our command, we would gladly quote, on account of the interest of this piece of telegraph history. We must content ourselves, however, with a single sentence from one of them, which gives the key to Sir William Thomson's two years later solution of the retardation difficulty. In his letter to the *Athenæum* of October 24th, 1856, the following remarkable sentence occurs (*after* he has made very clear indeed the difficulties to be expected). . . . "although I have never been able to learn any particulars as to the experience of those who worked that telegraph (Varna and Balaklava Cable), I have the best possible reason now for knowing that, if nine letters per second have not been delivered by it, the fault, or rather I should say, the deficiency, has not been in the cable, but in the instruments." A week later, December 11th, 1856, a short Paper was communicated to the Royal Society, "On Practical Methods for Signalling by the Electric Telegraph."

The warnings of Thomson were not, however, accepted, and it was only when the 1858 cable was *completed* that the directors became thoroughly alive to the situation. Whitehouse, experimenting on the cable itself with the Morse instrument, and endeavouring to transmit a column of *The Times*, found that he was unable to send through it at the rate of *one word per minute*. Then the directors sent for Thomson, and demanded of him that he would give them, according to his knowledge and his promise, an instrument which should satisfy the conditions necessary for success.

Thomson, experimenting with the reflection of the image of a candle thrown from his concave eyeglass on a sheet of white paper in a fairly lighted room, judged that the flame of a paraffin lamp reflected from a silvered mirror of one-tenth of that area would give an image bright enough for conveniently reading telegraphic signals. This was the first idea of the mirror galvanometer. The trials were made in February, 1858, and the mirrors and the instruments were made by Mr. James White, a Glasgow optician, whose name is now familiar to every electrician. The mirror galvanometer was supplied for the 1858 cable. The directors of the Atlantic Company insisted that Thomson should go to sea with the expedition, and also that he should take a patent for his instrument. This was done, and the patent then taken out was the first of Thomson's many patented inventions. To take a patent was somewhat against his wishes. He was ready freely to give to the public the fruit of his labours; and the same remark applies to at least two others of his most remarkable inventions—the Sounding Machine and the Mariners' Compass. Sounding by pianoforte wire was offered to the Admiralty, and was described in *The Times* directly after the loss of the "Schiller," and the compass was also freely offered; but he found in each case that the only way of securing attention to inventions of importance was to patent them and work the patents. Returning to ocean telegraphy: in 1867 the siphon recorder was invented and patented, and three years later was brought into very general use. Up to the present time these two are the only instruments by means of which signals are read on the long submarine lines.

We have just mentioned the Sounding Machine and the Mariners' Compass. The perfecting of these instruments gave Sir William Thomson much labour and thought through the years from 1872 to 1876. Both of these inventions were made to fulfil demands which he had seen to be urgent, partly in the course of his cable-laying expeditions, and partly through his knowledge of navigation, a subject in which he has always taken a very deep interest. In 1876, with the same thought at heart, he published "Tables for Facilitating the Use of Sumner's Method for Finding the Place of a Ship at Sea." The general adoption of Sumner's method thus made simple for the navigator would be a reform in navigation greatly to be desired.

Space fails us to give a full account of Sir William Thomson's more recent work. For five or six years his inventive genius has occupied itself with problems in electricity transcending in difficulty, we may safely say, any previously offered to inventors. To produce instruments capable of being used in the still novel work of electric lighting and electric transmission of power is the question of the day for many minds of high order. If we content ourselves with a 1 per cent. accuracy, or an accuracy of 1½ per cent., the problem is, perhaps, not too difficult to be satisfied with somewhat ordinary instruments, though most of the measuring instruments at present offered to users will scarcely be found to be reliable to this extent when fairly tested. Sir William Thomson, however, is not content with a standard so inferior; and his electric balances, which have recently and from time to time been described in these pages, certainly reach a far higher degree of trustworthiness.

A mere mention must now suffice of some interesting points in Sir William Thomson's history. In 1876, he was, in Philadelphia, a judge at the Centennial Exhibition. In 1880 he was, at Paris, a delegate to the Electrical Standards Conference, and at this time he was decorated Commander of the Legion of Honour of France. In 1883 he was in Vienna, at the International Exhibition; and in 1884 he received from Berlin the "*Ordre pour le Mérite*." In 1884 he once more crossed the Atlantic to deliver a course of lectures "On Molecular Dynamics," at Baltimore, to a "class" composed mainly of Professors from different parts of the world gathered together at the Johns Hopkins University.

Sir William Thomson is an honorary graduate of half the Universities in Europe. He is a Fellow of the Royal Society, President of the Royal Society of Edinburgh, Member of the Institut de France, the Accademia dei Lincei at Rome, the Berlin Academy, as has been already mentioned, the Amsterdam Koninklijke Akademie, the American Academy of Arts and Sciences. He has a multitude of medals, gold, silver, bronze, iron, awarded for various Papers and inventions, and numbers of addresses of greeting and congratulation.

Of himself, we will only say that his genius is at the least equalled by his gentle kindness and his single-minded modesty of disposition. These qualities are conspicuous in his daily intercourse with his students and his younger fellow-workers; and they make him the most beloved of teachers and associates.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

SIR WILLIAM THOMSON'S PRESIDENTIAL ADDRESS.*

"Electricity, Ether and Ponderable Matter."

(Continued from page 306.)

The telephone, one of the added subjects of the Institution of which we are members, illustrates very splendidly these developments of the theory of the transmission of signals through the submarine cable. The telephonic signals have, in fact, sufficient frequency to make electro-magnetic induction very sensibly influential. The frequencies in telephony correspond to from 250 periods per second up to two, or three, or four times that; being the frequencies involved in speaking in the human voice —tenor and soprano—and in the quality of the voice as affected by the over-tones. I say frequencies of from 250 per second to 1,000 or 1,500 periods per second are concerned in the

* Revised by Sir William Thomson.

Digitized by Google

fundamental notes, and in the characterising over-tones, of the sounds transmitted by the telephone. Now, there seems no doubt but that the clearness of the telephone through great distances is to a large degree due to the circumstance which Heaviside has pointed out—that we have much less of difference of attenuation and difference of phasal retardation, for different notes, with the actual frequencies of the notes in sounds transmitted through the telephone wire and the practical dimensions of the telephone wire, than we should have without electromagnetic induction (hear, hear).

I cannot speak on this subject without just touching upon a question which I do not at all propose to enter upon to-night, and that is, the relative efficiencies of iron and copper as telephonic conductors. Information given to me by Mr. Bennett, the engineer of the National Telephone Company in Scotland, leaves no doubt whatever but that there is a very considerably greater loss of clearness in speaking through an iron wire—such, for instance, as the first metallic circuit iron wire of the Post Office between Glasgow and Edinburgh—than there is in speaking through the present copper wire circuit of the Company between the same stations. I shall say nothing more of this just now. It is an exceedingly difficult and complicated subject. But Heaviside's mathematical work, and Lord Rayleigh's experimental investigations on the susceptibility of iron to very small differences of magnetic force, differences of magnetic force superimposed on even a powerful magnetic force or a large residual magnetism, put us, I think, in a very hopeful condition. The subject is in good hands, mathematical and practical, and I think before many months pass over the Institution of Electrical Engineers we may have an absolutely clear understanding of telephony through iron wire as compared with telephony through copper wire (applause).

Leaving all questions of submarine telegraphy, and of telegraphy or telephony, in which, whether from the greatness of the distance through which the communications are made or smallness of distance between insulated conductor and sheath, or between the twin wires when insulated metallic circuit is used, the effects of electro-static capacity give rise to sensible difference of strength of current in different parts along the length of the conductor, I wish to call your attention to the differences of current density across different parts of the cross section which are produced when alternate currents are sent through a wire. Consider a copper wire and a copper tube surrounding it for return. Or consider what is, after all, one of the very simplest cases, two parallel copper wires. If the distance between them is a large multiple of the diameter of each, as is the case in practical telegraphy and telephony, the problem is the same as the problem of a single copper wire in the centre of a cylindrical tube of infinitely conductive metal, and of radius equal to the distance between the wires. The distribution of current within the solid conductor depends only on the period of the alternations, and on the diameter and the specific resistance of the metal; and is quite independent of the surroundings, provided only they be symmetrical all round, or provided, if the case be that of two parallel wires, the distance between the two wires be a large multiple of the diameter of each, so that the current in each is not sensibly disturbed by the influence of the other from being arranged in co-axial cylindric layers of equal current density. For this problem the mathematical theory gives us a remarkably interesting and very useful practical result, and I really, in proposing to speak upon such a very abstruse and uninteresting subject as electricity, ether, and ponderable matter, wish to try to give one little piece of practical information to night. It will be no information to some, but it may be information to others (hear, hear). The solution, expressed in a formula, and a table of numerical results calculated from it, I hope, will appear complete in the report of this address. I think I might give you just now two or three of the numbers that are rather interesting. Take 80 periods per second as the frequency—that is about what is adopted in the alternate-current system of distribution for electric light: at all events in one great system I know, the Grosvenor Gallery installation, that is the frequency of the period; and I believe it is pretty much the same generally. Let us take, then, as an example, the 80 periods per second. First, consider copper wire of one centimetre diameter: the ohmic effective resistance is greater than for steady current through the same wire, but not as much as $\frac{1}{100}$ per cent. greater. Take, now, copper wire of $1\frac{1}{2}$ centimetres diameter; the ohmic effective resistance is $2\frac{1}{2}$ per cent. greater than the resistance for steady current. Next, take copper wire of 2 centimetres diameter; the ohmic resistance is 8 per cent. more for the alternating current than for the steady current. In round copper rod of 4 centimetres diameter the ohmic resistance is 68 per cent. more for the 80 periods per second alternate currents than for steady currents. In round copper bar of 10 centimetres diameter the ohmic resistance is 3·8 times what it would be for the steady current. In a solid copper cylinder of 100 centimetres diameter the ohmic resistance is 35 times greater than for steady currents. From 10 centimetres diameter upwards the ohmic effective conductance—that is, the reciprocal of the ohmic effective resistance—increases scarcely more than as the diameter simply, and not as the square of the diameter. The conductance for steady currents is as the square of the diameter all through. The effective conductance for alternate currents follows a law which can only be expressed by aid of Fourier-Bessel functions till we get to very great diameters. When we get to so great a diameter that the shell, or outer portion, of the wire into which the current is practically confined is moderate or small in proportion to the diameter of the wire, then, for diameters exceeding that, you can all see perfectly without calculation that the conductance is in simple proportion to the circumference, and therefore in simple proposition to the diameter. This very imperfect explanation of the results may give some idea which, I think, is of rather an interesting and important kind, but the figures will speak for themselves (hear, hear). With quadruple frequency the same figures apply to wires of half diameter. There we get the telephone problem. Four times 80 is 320, which is among the frequencies for telephonic notes: and for the 320 frequency, take the figures I have given, but with half the linear magnitudes. Thus, for instance, for copper wire of 1 centimetre diameter, transmitting musical notes of 320 periods per second, the ohmic resistance is 8 per cent. greater than the resistance for steady currents. For a copper wire 2 centimetres diameter, and frequency of musical note 320 per second, the ohmic resistance is 68 per cent. greater than the resistance for steady currents, and so on.

Another important development from this theory is that there is much less importance in the conductivity of the metal for telephonic work through extreme distances, than for ordinary electric work. The formula and figures showing the kind of relations between ohmic effective resistances for different speeds are, as we have seen, a little complicated; but I will only say that ultimately it is the square root of the resistance that we have to deal with instead of the simple resistance. Quadruple resistance is only twice as bad, speaking roughly, when the frequency is so great as to cause the effect of the ohmic resistance to be very much greater than the resistance for steady currents. The moral of this is, not that you may choose wire of bad conductivity; on the contrary, take the best conductivity you can get, whether for telephones or for electric light conductors, but shape the conductors so that the ohmic resistance shall not be too much augmented by the unequal distribution of the current.

In respect to electro-magnetic theory. We have a very fine analogy with viscous fluid motion which has been obvious, more or less, from the time the known laws of electro-magnetic induction were put into formulæ in the beautiful manner in which Max well put them—we have a very fine analogy, I say, with the diffusion of laminar motion into a viscous fluid and its analogue in the diffusion of heat by conduction through a solid, first pointed out by Prof. Stokes (applause). The actions concerned in the distribution of alternating electric current through a conductor such as copper, and the distribution of the motion of water in a viscous fluid disturbed by periodical tangential motions of its surface, follow identically the same law. Mr. Heaviside, referring to this, has well said that this analogy is very useful, because we can see the motions in a viscous fluid and understand them, and picture them to our minds, while it is much more difficult to fancy we see the distribution of electric

Digitized by Google

current in a wire. Take, now, definitively this analogy for the distribution of electric current in a round copper wire through which alternate currents of electricity are sent. Take a viscous fluid in a tube in place of the conductor: move the tube to and fro with a regular alternating motion—a simple harmonic motion. In order that we may fulfil at all approximately what I am speaking of, the length of the tube must be very great in comparison with the diameter, and the place in which we consider the motion of the fluid must be at a distance of many diameters from the ends which we may suppose to be closed by frictionless pistons, limiting the fluid at its two ends. In the first place, if the fluid were not viscous, if it was perfectly liquid, you might move the tube to and fro; but the fluid inside of it would remain at rest. Water, however, would move; oil would move; the more viscous the fluid is the more liable it would be to experience motion in that way. Now, there is a perfect analogy between the alternating motion of the fluid transmitted inwards from the surface and the distribution of the electric current in a wire through which the effect of the alternating current machine is being conveyed.

Another very interesting analogy in which exactly the same law holds is the change of temperature of a conducting solid due to variations of external temperature. Imagine a column of rock or stone or metal, and, instead of moving our tube to and fro longitudinally, let the atmosphere surrounding our column be periodically varied in temperature; the law of the inwards progress of changes of temperature, the law of the maximums and minimums, and zeros of temperature, is identical with the law of the corresponding features of electric currents and of fluid motion. In each case we have a propagation inwards, with diminishing amplitude. In each case the rate of diminution of amplitude corresponds to the retardation of phase according to exactly the same law. I need not attempt at this time to state the law—mathematicians know it perfectly well. Now take another case. Here the thermal analogy absolutely fails us, but the fluid motion analogy still holds. Take a tube of fluid and give it an alternating motion—a periodically-varying motion round its axis which gives a tangential drag to the fluid in the inside. Now you can all see that the inwards penetration of the tangential drag, if the alternations of the motion be very quick, will follow the same law for the to and fro motion of the cylinder and for the rotatory motion of the cylinder. The question is this: Does the variation penetrate sensibly to a large distance in from the outside or not? If, for example, it penetrates in only the one-hundredth of the radius, then it is obvious that we shall have sensibly the same law of penetration inwards for the disturbance, whether for the case of the rotatory motion of the cylinder round its axis or of longitudinally to and fro motion. Exactly the same thing holds with reference to electro-magnetic induction. The one case of electro-magnetic induction that I mentioned first is the most important, being the telegraph and telephone case, but another very interesting case, and not at all without practical importance, is the penetration of induced currents into a copper or other metallic core within a solenoid. Take a common helix or solenoid: send an alternating current through its coil—you know what it does. It produces magnetic force, with lines of force parallel to the axis in the interior of the solenoid. But alternating magnetic force, through the copper, induces electric currents in circles perpendicular to the direction of the force. Thus we have currents induced as you all very well know in a solid metal core of a solenoid. A metallic core other than iron is a subject for investigation of an exceedingly easy kind. The Fourier-Bessel functions come in here just as they do in the other cases in which we are concerned with circular cylinders. If we have, instead of copper, an iron core, we must take into account its inductive magnetisation. This presents no *mathematical* difficulty if we suppose the magnetic susceptibility constant: and the same law of amplitudes and phasal retardation holds as for copper or other non-magnetic metal. The difficulties, both experimental and mathematical, to take into account the enormous differences of the inductive quality of iron with different degrees of magnetisation, and with reversals of magnetisation, and the great complications of the inductive effects on account of the "magnetic friction" in the iron introduce corresponding complications in the theory of the induced currents, and they are complications of a kind that are very formidable.

Now I can only just go on to say two or three words about an extension of that viscous fluid theory that allows us to take into account all that goes on both in air and in metal, and in different metals, whether in contact with one another or separated by air. For illustration, consider our two simple cases—parallel wires with alternating currents through them, and the cylinder rotated with a periodic motion of rotation alternately in opposite directions. The analogy is simply this. To represent different metals, densities of fluid in simple proportion to the electric conductivities must be taken. The viscosity must be the same in all. The representative of an insulator in this analogy is a massless fluid. By "massless" I mean devoid of inertia—perhaps I ought to say an "inertialess" fluid, because people attach other ideas to "mass" sometimes than "inertia," but in the strictest dynamical language "mass" is taken as the measure of inertia. An inertialess viscous fluid must take the place of air or other non-conductor; a viscous fluid of a certain density, but the same degree of vicosity, must take the place of lead. A fluid of twelve times the density of lead would take the place of copper, the conductivity of copper being, say, twelve times the conductivity of lead.

Time does not allow me to pursue the subject further in the way of illustration at present, but I must return to the second case later on, because I am going to speak of iron and rotation.

Now with reference to the electrostatic effect, the hopeless—I must not say "hopeless"—that is too large a word; we are never without hope in science (hear, hear)—I was going to use another word "despair;" well, I feel it desperately difficult, I feel the probability of my seeing the solution of it *is* hopeless. To merely introduce into the analogy electrostatic effect is very simple. Simply imagine an interface between the two fluids and give it such stiffness against change of shape as is required to cause it to fulfil the conditions which electrostatic knowledge and our knowledge of the laws of electric and electro-magnetic influence dictate to us. I say put in at the interface the requisite normal force, and you can extend the analogy to include the complete problem of the submarine cable, in which electromagnetic and electrostatic induction are both taken into account. But it is only by putting in, and in an arbitrary manner, a force at the surface to fulfil the requisite conditions, that we can complete the analogy.

The analogy I have just sketched cannot be considered as being in any respect a physical analogy. In it the analogue to electric current is not velocity of the fluid, it is not the molecular rotation of the fluid, it is a quality derived from the simple motion of the fluid; mathematically by the operation known as the laplacian operation—the laplacian of (u,v,w) is the electric current. Another way of putting it is the rotation of the rotation of (u,v,w), or the spin-flow of the spin-flow of (u,v,w). The word "curl" was introduced by Clifford and Maxwell, and has, I grieve to say, been adopted by Mr. Oliver Heaviside. It is the curl of the curl. I object to "curl," because "rotation" or "spin" is good and "curl" is bad; I object to it on that ground, but not only on that ground. I object to it also because it is connected with a kind of mathematical symbolism which seems to me not desirable and not instructive, and, above all, not convenient for any practical use in mathematics. This "laplacian" is too difficult a subject to explain, but I would by a case try to illustrate it. Take in the viscous fluid analogue what corresponds to the steady current in a wire. Think of the tube with viscous fluid and pistons as before. At one end of the tube press a piston in with a uniform motion, continued long enough to cause the fluid throughout the tube to come to a state of steady motion. In the neighbourhood of the piston the motion is disturbed by the rigidity of the piston; but go to a distance of ten or twenty diameters from the piston, and the motion of the fluid takes a perfectly regular character. (*Illustrating on black-board as Fig. 1*). Suppose *that* to be the inner surface of the tube. This dotted line represents a portion of the liquid which at one time is plane. A little later, while the fluid in contact with the containing surface remains unmoved in the doctrine of viscous fluid, as given by Stokes,

Digitized by Google

there is absolutely no slip at the containing surface, this portion of the fluid, which was plane, becomes the paraboloid of revolution, which you see shown in axial section in the diagram. The velocity of the fluid is nothing at the bounding surface, and it is a maximum at the centre. Well, we have two functions derivable from the consideration of that distribution of velocity. The first is the rate of shearing of the fluid; the second is the rate of change per unit-change of distance from the axis of the rate of shearing.* The rate of shearing represented graphically is equal to the tangent of the inclination (T P N) of this curve to the transverse surface—the tangent of the inclination of the curve, being the angle which is represented by the letter i. Now, the rate of change from point to point of the rate of shearing is the analogue to the strength of the current, and that is uniform. So in this analogy of a viscous fluid forced through a tube we have not the fluid velocity equal to the electric current, but something else, quite intelligible; and the reason for it, in our analogy, is clear enough. But there is something interesting, perhaps, in this idea, that we have a super-subtle mathematical definition of electric current which is not fluid velocity. Well, now, perhaps someone will say, "Had not we better get an analogy in which a fluid velocity is equal to the velocity of the electric flow?" Well, I do not say whether we had better do so or had better not, but we do not otherwise than in the way I have defined get the working analogy; and there is an advantage in this analogy. It gives us a motion of which the rotation is the magnetic force. Mr. Heaviside rather overlooks that. He objects to Maxwell's vector-potential; I do not agree with him in his objection. If he had confined the objection to the "vector" and the "potential" (vector wholly bad, and potential bad in connection with the

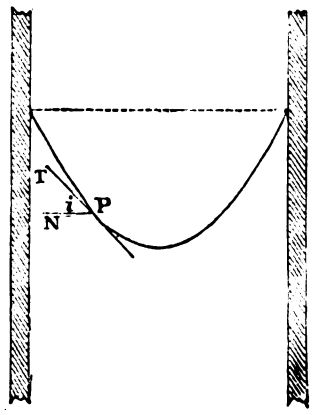

Fig. 1.

present subject), I would heartily have agreed with him, because I think it is an unhappily chosen name; but Maxwell's use of the thing (which he unhappily calls vector-potential) is most happy and most instructive, as it seems to me. Maxwell does not translate this into realities of motion, but he puts down in his formulæ as the foundation from which one step leads to magnetic force and the next step to electric current, something which translated into realities of motion gives us a motion of which the rotation is the magnetic force; and here it seems to me that if we are ever to have a real theory it must be founded upon this view. The hand of the clock warns me time is going on so rapidly that we must leave this analogy absolutely unfinished. Perhaps it is well to be obliged to leave it now, because the more we look at it the less we like it if we wish to see and to like a true mechanical explanation of electro-magnetism. The work is done in the wrong place. In the dense liquid, work is done, and heat generated in proportion to the square of the rate of shearing. In the electric analogue the work is done, and heat generated uniformly throughout the conductor. We have work done and heat generated in the viscous massless fluid taking the place of the dielectric in our fluid analogue. We must discredit that absolutely; but the reason for judging the analogy worth so much notice as even it has had to-night is that it is a perfect mathematical working analogy, and an exceedingly useful and instructive kind of analogy; and a very potent one to help us in guessing out, and in thinking out, and estimating results in practical problems of electro-magnetic induction in dynamos and in alternate-current machines, and in telephones and in electric instruments of great varieties of shape and mutual relations.

(To be continued.)

* Suppose the parabola in the drawing to represent the fluid which lay along the dotted line a unit of time earlier. The distance of P from the dotted line is equal to the velocity of the fluid (v), at the distance (r) of P from the axis. We have $u = c\,(a^2 - r^2)$; where a denotes the radius of the tube and c the fluid velocity along its axis. We have $\frac{-du}{dr} = 2\,c\,r$, which is the rate of shearing; and $\frac{-d^2u}{dr^2} = 2\,c$, which is our representative of the electric-current density. The whole strength of the electric current is $2\,\pi\,c\,a^2$.

Section III.—Magnetic Fields of Coils and Solenoids.

(Continued from page 249.)

143. *Preliminary.*—The phenomenon which may be considered the most important and fundamental to be appreciated

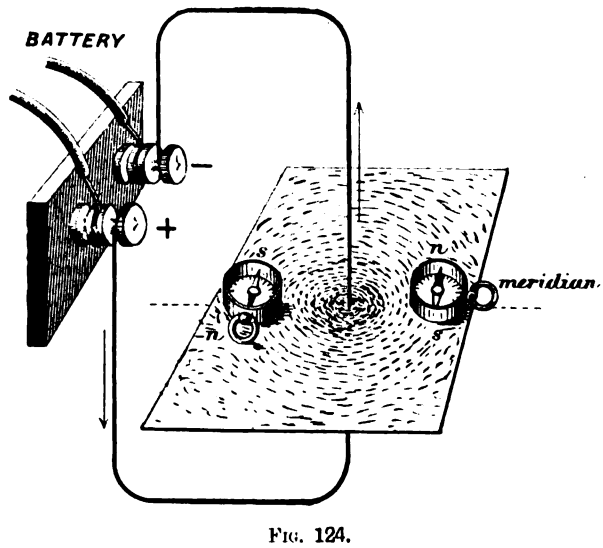

Fig. 124.

in dealing with this subject is that discovered by Oerstedt, of Copenhagen, seventy years ago, viz., the magnetic character of and effects produced by currents of electricity. A very simple experiment is sufficient to exhibit the magnetic field set up in the neighbourhood of a conductor carrying an electric current. A piece of stout copper wire, say No. 14, is pierced through the centre of a sheet of stiff cardboard (Fig. 124), and carried vertically for two or three feet before it is bent round to the terminals leading to a battery or other source of current. The card should be supported uniformly underneath, so as to present a flat, rigid surface, and the battery should consist of a few cells of large plate area, such as secondary batteries, in order to furnish a strong current. If the latter are used there should be an adjustable resistance between the battery and the experimental wire, which can be gradually reduced until the current is of sufficient strength to exhibit the effects, otherwise the experimental wire, being of neligible resistance, short-circuits the cells. Iron filings sprinkled over the card while the current is passing arrange themselves in circles round the wire. This exhibits the form of the magnetic field surrounding a straight conductor conveying a current, and demonstrates the magnetic character and properties of the current. What most concerns us in the use of this principle is the measurement of the field; in other words, we must be able to calculate the intensity and direction of the field at any point

Digitized by Google

in the vicinity of the conductor. The direction of flow of the circular lines of force according to the usual assumption (para. 104) may be readily observed by exploring the same with a small magnetic compass-needle as shown in the figure. Suppose a line drawn across the card in the direction of the magnetic meridian, and two compass-needles placed on the line, one on each side of the conductor. Before the current is switched on to the wire the two needles will point along the meridian line, both, of course, with their north poles pointing towards the north. Now, if we connect the battery to the terminals, so as to send a current *upwards* through the wire, we shall observe on switching on the current that the needles move sharply into positions nearly at right angles to the meridian line, each pointing the opposite way. The north pole of the one on the right-hand side of the wire will point *away* from the observer, and the same pole of the other needle will point *towards* the observer, as shown. And if we move one compass needle round the wire, starting from one point and coming back to the same again, we shall observe that the needle turns on its pivot through a complete revolution—in other words, it shows the direction of flow of the curves of force to be continuous. According to the assumption that the north pole of a needle points to the direction of flow of the lines (para. 104), we find that, in this case, the flow is round the wire in the direction in which one would unscrew a screw (*a* Fig. 125). To remember the direction, perhaps the screw is the best analogy, for in unscrewing a screw we are moving it bodily upwards, *i.e.*, in the same direction as the current flows in the wire. The converse case (*b* Fig. 125) is with a descending current in the wire, the direction of flow of lines being reversed, and

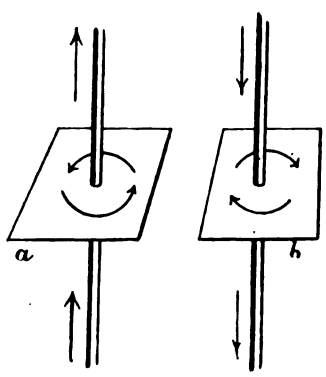

Fig. 125.

coinciding with the direction of turning a screw when screwing it downwards. Again, suppose we are using a spanner to screw a nut off or on a bolt, and we take the bolt to represent the conductor, and the direction in which the nut moves *bodily* along the bolt to represent the direction of the current in the conductor, then whichever way the bolt is placed, or in whatever direction the nut is moved, the direction of the circular lines of force round the conductor will always be the same as that in which the spanner is turned. The student will find it quite easy to recollect the direction of field for a given current by these practical analogies. In moving the needle round the wire it does not quite set itself as a tangent to the circle of force, because it is also affected by the earth's horizontal field, but with the strong current through the wire necessary to exhibit the circles of iron filings the earth's field has, in comparison to the circular field, very slight influence on the needle. It is this principle which enables us to find the direction of flow of a current in a conductor by the direction in which a compass needle, placed near it, sets itself (para. 66.) When a force acts along the circumference of a circle the *direction* of the force at any given point in the circumference is a tangent to the circle at that point, and this tangent is a line at right angles to the radius of the circle drawn from the centre to the point. If, therefore, we consider any one of the circles of force surrounding a conductor conveying a current, it is clear that, whatever point we choose in that circle, the magnetic force is acting there at right angles to the radius of the circle (drawn from the conductor to the point) and at a tangent to the curve. Further, if we consider two straight conductors side by side (Fig. 125), in which equal currents are flowing in opposite directions, it is evident that those portions of the circles of force which are between the conductors coincide in direction. The magnetic field at a point equidistant from both conductors, and in the same plane, is therefore twice the intensity of that which would exist if one of the conductors were removed—in other words, there would be twice the force acting on a magnetic needle placed at the point. But a still greater intensity of field may be produced at the point by bending the conductor into the form of a circle (Fig. 127), of which the given

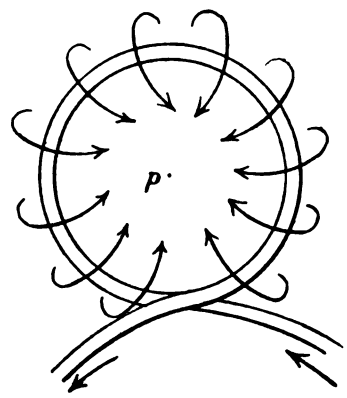

Fig. 127.

point is the centre. Here all the circles of force act in the most direct and efficient way, so as to add up their effects in one direction. This direction, by what has been said, will be understood to be entering the ring *from* the observer, the current being in the direction indicated by the arrows in the figure. The relative strengths of field produced (1) by the ring at its centre, *p*, and (2) by two very long straight conductors carrying the same strength of current, each of which is separated from the point by a distance equal to the radius of the ring (the conductors and the point being in the same plane), would be in the proportion of 2π to 4, or as 6·28 : 4. The same physical effect of multiplying the magnetic action by carrying the conductor completely round the point where the field is required, is obtained in the same way, whether the conductor is in a circular form or otherwise. We shall, however, confine ourselves to the circular form of conductor or coil, this being the general form for standard gal-

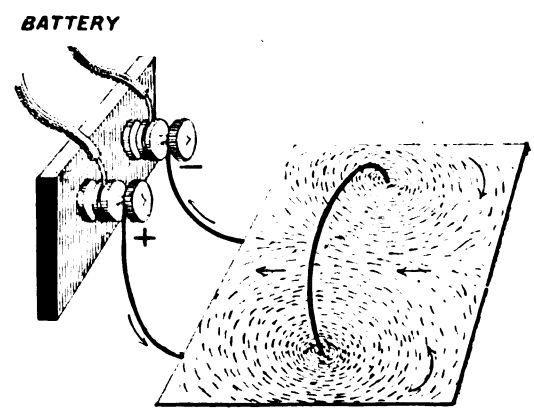

Fig. 126.

vanometers, and that which is the best for quantitively determining the magnetic field due to a current. The appearance of the lines of force, as shown by iron filings when the conductor is bent into a semi-circle, is shewn in Fig. 126, where the direction of the current and lines of force are indicated. The next step will be to point out the law by which the intensity of field in C.-G.-S. units due to a current may be determined, and to instance its application to solenoids and galvanometer coils.

REVIEWS.

The Electric Motor, and its Applications. By T. C. Martin and J. Wetzler. (New York: W. J. Johnstone, 1888. Second Edition. Enlarged.)

We are pleased to see that a second edition of this valuable work has already been demanded. The opportunity has been taken to add four new chapters, which include descriptions of the latest European and American motors, both for direct and alternating currents. Most, if not all, of this information has already appeared in the columns of our contemporary, *The Electrical World*, of New York, but it is none the less welcome in volume form. Amongst the more important contents of the new chapters we may mention the very full description of the Bentley-Knight Electric Railway Company's System (see *The Electrician*, January 21, 1887, p. 240), comprising both overhead and conduit conductors; the Field Electric Locomotive and Street Railway System (see *The Electrician*, March 18, 1887, p. 419), the Short-Nesmith Series System (see *The Electrician*, April 29, 1887, p. 549), Irish's Conduit System (see *The Electrician*, January 6, 1888, p. 219), Schlesinger's Mining Locomotive, and various small motors designed for light work. The Lugo motor (see *The Electrician*, July 27, 1888, p. 385), in which the armature contains salient poles, would be regarded in this country as a decidedly retrograde step. On page 221 we read that a Schlesinger motor "designed specially for locomotives having to haul heavy loads" weighs with its gearing only 1,500lbs., and gives an output of 35 horse-power, or 1 horse-power for every 43lbs. of dead weight! This is a magnificent performance, and we should very much like to know how it is done. One of the most interesting and novel arrangements is that of Lieut. Patten, in which the armature is wound with three coils only, all of which are continuously in circuit in parallel with one another. Amongst other advantages claimed for this arrangement is that of absolute non-sparking for all positions of the brushes. The Immisch motor is described for the first time in this edition, but the particular machine described represents quite an early stage, beyond which Messrs. Immisch have advanced long since.

The chapter on "Alternating-Current Motors" contains an account of the interesting experiments of Prof. Elihu Thomson, which are based upon the peculiar action first investigated in this country by Dr. Fleming (see *The Electrician*, May 6, 1887, p. 561). This is followed by a reprint of the well-known Paper of Mr. Nikola Tesla, in which, however, it should be noted that the particular form now adopted by the Westinghouse Company is only incidentally referred to. The actual Westinghouse motor is not figured at all. The chapter ends with the statement that shortly after the publication of Mr. Tesla's work Prof. Galileo Ferraris published an independent investigation of the same kind. In the interest of chronological accuracy in this sentence, for the word "after" we must read "before." Prof. Ferraris' pamphlet reached this country in April, 1888, whereas it was not until May 15 that Mr. Tesla's Paper was read before the American Institute of Electrical Engineers.

The last chapter is devoted to Pyro-Magnetic Motors, and contains an account of practically all that has up to the present been done in this direction. It will be remembered that this subject was considered somewhat fully in *The Electrician*, Vol. XX., and the first description of M. Menges' ingenious motor appeared in our issue of January 13, 1888, p. 231.

In conclusion, whilst fully appreciating the value and importance of this work, we have to express our regret that in the issue of a second edition the authors have not thought it necessary to remove the theoretical mis-statements to which we called attention in our review of the first edition. It is really unfortunate that a work characterised by so much intelligence, and brimful of practical information, should retain such singular calculations as those of Mr. Rae in Chapter IV. We hope to see this section either omitted or entirely re-written in the next edition.

Die Erzeugung und Verteilung der Elektrizitat in Zentral-Stationen. By Dr. Mortin Krieg. (Magdeburg: A. and R. Faber.)

At the present moment it is not open to question that of all European countries central-station electric lighting has taken the firmest root in Germany; there is, therefore, plenty of ground for the production of the book before us. The preface states that its object is to be useful both to the engineer and the non-technical reader. Although interesting to foreign engineers, as giving some idea of German work, we fancy a German engineer will principally use it as a present to the ruling powers of the place in which he may wish to start a central station. There is just enough technical matter in it to make an outsider think it is a practical, not a popular work, and that he is very clever to understand as much as he does; while at the same time he learns that there is much quite beyond him, and that he must leave to the professional engineer. From the opening chapter on dynamos, which is very fully illustrated, we gain a good general idea of the "Dynamo Teutonicus." Taken as a whole, it is less remarkable for beauty than it is for strength, not to say dimensions, and perhaps originality is the kindest way of expressing another striking feature in many of the illustrations.

By-the-bye in the hybrid "D Teutonicus" and "D Americanus" the illustrations show the magnets formed of six vertical legs, as in the earliest Edison machines; surely this cannot be correct at the present day. Pretty full data are given of the various machines, and also of many of foreign manufacture as to output, efficiency, &c.

We must congratulate the author for his straightforwardness in reproducing one little remark concerning the Frankfort Gas Company's installation, viz., that the reason for employing English engines, boilers, and dynamos was that the contractors (not an English firm) had to guarantee the working of the installation.

The chapter on accumulators is to the point, but contains nothing very novel. The various systems of direct-current distribution are next discussed—series, parallel, three-wire, &c., with their various advantages; the disadvantages are generally not fully pointed out, which is a great mistake in a book of this sort. For example, a saving in the cost of mains of 43 to 45 per cent. (*sic*) is claimed for 7 and 10 wire systems; as if these were in any sense of the word practical systems. Diagram 43, representing an installation with batteries, is just what we should expect a learned professor to put down the first time he attempted practical work.

A number of more or less (principally more) complicated regulating devices are illustrated. We should be surprised if any one of them were to be found in a central station ten years hence, even in Germany.

According to Dr. Krieg there are only two makers of leads in Germany worth mentioning; that is no reason, however, for devoting a whole chapter, with illustrations, to matter whose proper place is in the said makers' catalogues. The Germans have always gone in for cheap and rough forms of instrument—rough, that is, in outward appearance—and several of the well-known forms are here described and cuts given of the outside appearance. When such a number of illustrations of unpractical devices are included it is a pity that none of the internal arrangements of the really practical ones are to be found. The meter exploited by Dr. Aron is well described, but no mention is made of the inventors, Profs. Ayrton and Perry.

We now come, when well past the middle of the book, to the nominal subject thereof—central station lighting. This is divided into three chapters, beginning with a recommendation that the town should lay down the installation, and then farm it out to a contractor for ten years. The arguments adduced on behalf of this suggestion are not very convincing. The rest of the chapter is principally a reproduction of Herr Fritzche's Paper in the *Centralblatt* in the beginning of last year.* In the most interesting chapter in the book—that descriptive of existing stations—while giving America credit for being first in the field, the author claims for Milan the honour of being the first town to start a central station in Europe.

Detailed descriptions are then given of a Westinghouse central station for 2,400 lamps at Trenton, N.Y.; two Berlin stations of 6,000 and 8,000 lamps; and Lubeck about 4,000

* An important extract from this Paper, showing curves of output for every month in the year for a Berlin station, will be found in *The Electrician*, June 29th, 1888, p. 244.

Digitized by Google

10 candle-power. (It is instructive to compare the simplicity of the Trenton station with the extreme—otherwiseness, shall we say?—of this one.) The stations at Elberfeld, Amsterdam, and Ehrenfeldt are then described, as well as several now building; in fact, this chapter gives a good idea of the present state of things in Germany, and will doubtless be read with interest by many engineers in other countries. The great fault in most of the German centrals described appears to be complication. What is now wanted is for Teutonic engineers to go to the States for a while and learn simplicity.

The final chapter gives some methods for calculating networks, both graphically and analytically. A good deal of it is drawn from Herr Fritzche, and some of it, we think, we have seen in English some years ago. Though not really very complicated, it is calculated to impress upon the non-technical reader that the working out of networks is an unholy amusement which he had better leave entirely to his professional adviser. Perhaps this is the author's intention.

"The Bell Hanger's Handbook." (By F. B. Badt. Electrician Publishing Company, Chicago, 1889.)

This is a capital little book, giving the most detailed and explicit instructions for the fitting of all kinds of electric bells, annunciators, fire alarms, gas lighting fixtures, and other small fry of the same kind. It is abundantly illustrated, and ought to prove very useful to the class for whom it is intended.

TANGENT FUNCTION MULTIPLIERS TO BE USED WITH THE KAPP FORMULÆ IN THE DESIGN OF DYNAMOS AND MOTORS.

BY ALBION T. SNELL.

The armature iron is assumed to be saturated with 26 Kapp lines or 25,000 C.-G.-S. units, and the field-magnets with 18 Kapp lines or 17,300 C.-G.-S. units.

24	23,049	5·61	
25	24,010	10·82	
26	25,000	infinite	

In using the above multipliers the value of the magnetic resistance of the armature and field is first determined from the drawing or actual measurements, as detailed by Mr. Kapp. A suitable magnetic flux is then chosen. In the armature, say, $Z_a = 2\,a\,b\,\mu_a$, where a = the depth of the armature core, b = the length of the iron *less the insulation*, and μ_a = the number of lines per unit of area. The coefficient of leakage is assumed to be known or can be determined by experiment. This usually varies between 1·25 and 2·00. Z_a is then multiplied by this coefficient, and gives us Zf, which is the magnetic flux in the field-magnets.

The values of the armature and field-magnet resistances have now to be multiplied by the multipliers corresponding to the values of μ_a and μf ($\mu f = \frac{Zf}{\text{cross section of field}}$).

We have now $n\,c = \frac{Zf}{k\,R_a + k_1\,r_a + R'}$

and the number of ampere-turns to give Zf is known.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-night) FRIDAY, January 25th.

Institution of Civil Engineers.

7:30 p.m. Students' Meeting. Paper to be read, "Water Softening and Filtering Apparatus for Locomotive Purposes, at the Taff Vale Railway Company's Penarth Dock Station, near Cardiff." By W. W. F. Pullen, Stud. Inst. C.E.

Society of Arts.

8 p.m. Indian Section. "The Asiatic Colonisation of East Africa." By H. H. Johnston, F.R.G.S.

Electro-Harmonic Society.

8 p.m. Smoking Concert at the St. James's Hall Restaurant.

Royal Institution.

9 p.m. "Meteorites and the History of Stellar Systems." By Prof. G. H. Darwin, M.A., F.R.S.

SATURDAY, January 26th.

Royal Institution.

3 p.m. Afternoon Lecture, "The Character of the Great Composers and the Characteristics of their Works." By Prof. Ernst Pauer.

Physical Society.

3 p.m. Notes on "Polarised Light," on "The Structure of Natural Diffraction Gratings of Quartz," on "Ahrew's Modification of Delezenne's Polariser," and on "The Use of Two Quarter-Wave Plates in Combination with a Stationary Polariser;" and a Note on "A Relation between Magnetisation and Speed in the Dynamo Machine." By Prof. S. P. Thompson, D.Sc.

"On the Divergence of Electromotive Forces from Thermo-Chemical Data." By Prof. E. F. Herrmann.

MONDAY, January 28th.

Society of Arts.

8 p.m. Cantor Lecture II., "Egyptian Tapestry and Textiles." By Alan S. Cole.

TUESDAY, January 29th.

Royal Institution.

3 p.m. Afternoon Lecture, "Before and After Darwin." By George John Romanes, M.A., F.R.S.

Institution of Civil Engineers.

8 p.m. Papers to be read, "The Steep Incline on the Puerto, Cabello and Valencia Railway, Venezuela," by John Carruthers, M.I.C.E.; "Cost of Working the Hartz Mountain Railway," by Robert Wilson, M.I.C.E.; "Further Information on the Working of the Fell System on the Kimutaka Incline, N.Z." By J. P. Maxwell, M.I.C.E.

Society of Arts.

8 p.m. Foreign and Colonial Section, "Gold and Silver Mining in Colorada." By T. W. Goad.

WEDNESDAY, January 30th.

City and Guilds of London Institute Old Students' Association.

7:45 p.m. Meeting at the Central Institution, Exhibition-road. Discussion on Mr. Albion T. Snell's Paper on "The Design of Electro-Motors."

Society of Arts.

8 p.m. Ordinary Meeting. "The Construction of Photographic Lenses." By Conrad Beck.

THURSDAY, January 31st.

Royal Institution.

3 p.m. Afternoon Lecture, "The Metamorphoses of Minerals." By Prof. J. W. Judd, F.R.S.

FRIDAY, February 1st.

Royal Institution.

9 p.m. "The Life History of a Marine Food Fish." By Prof. W. C. McIntosh, M.D., F.R.S.

***** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.**

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714.

All Communications to be addressed to "The Electrician," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician."

All letters intended for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.

"The Electrician" is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.

SPECIAL NOTICE.

Owing to the increase in the number of pages of "The Electrician," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For Foreign Parts and Colonies:— Within Postal Union	6 6	12 6	24 0
„ Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"The Electrician" offers exceptional advantages to Advertisers. **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Trade Advertisements *intended for the current issue must be handed in not later than First Post on Thursday morning.*

Small Prepaid Advertisements *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"The Electrician" Printing and Publishing Company (Limited) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "The Electrician" Electrical Trades' Directory and Handbook. The Directory was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.

THE DIRECTORY for 1889 will SHORTLY BE READY.

CONTENTS OF THE CURRENT NUMBER.

Supplement to this Week's Issue.

A STEEL-PLATE PORTRAIT OF SIR WILLIAM THOMSON, F.R.S., &c., &c., President of the Institution of Electrical Engineers.

Notes 325
Sir William Thomson 330
The Institution of Electrical Engineers.—Sir Wm. Thomson's Presidential Address. Illustrated. Continued 331
Letters for Learners and Un-Professional Readers. By H. D. Wilkinson. Illustrated. Continued 334
Reviews 336
Tangent Function Multipliers to be used with the Kapp Formulæ in the Design of Dynamos and Motors. By Albion T. Snell 337
Meetings of Scientific Societies. 337
The Aurora Borealis 338
The Insulation Resistance of Electric Light Installations. By Prof. A. Jamieson. Illus. 340
Legal Intelligence—
In re Gaulard and Gibbs' Patent.—Appeal. 343
The Electric Lighting of Dieulefit and Valreas. Illustrated. 345
American Notes 346
Notes from Paris 347
Notes from Brussels 347
Correspondence—
Telegraphy without Wires.—A. A. Campbell Swinton ... 348
Correspondence—*Continued.*
Mr. Edmunds' Method of Maintaining Constant Current.—Henry Edmunds and R. H. C. Neville 349

City Notes, &c. 355
Companies' Share List 356

SPECIAL NOTICE.

With this number of "The Electrician" is published a Supplement Steel Plate Portrait of Sir William Thomson, F.R.S., President of the Institution of Electrical Engineers.

"Electrician" Subscribers should receive this Plate Gratis. To non-subscribers the price of this issue of "The Electrician" is Sixpence.

Subscribers should promptly address complaints of non-receipt of the Portrait to The Publisher.

A few copies of The Portrait, on large Paper, neatly framed in Brown or Black, will be supplied (carriage paid) for Four Shillings and Sixpence. Early application is necessary, as the number of copies is limited.

THE AURORA BOREALIS.

Our knowledge of the phenomena of terrestrial—and still more of cosmical—electro-magnetics is confessedly meagre in the extreme. Terrestrial magnetism, earth currents, atmospheric electricity, and the Aurora Borealis, all present a wide field for speculation and research. That electrical forces also play an important part in the solar economy is indisputable; but the physical conditions are so utterly unlike anything of which we can obtain an experimental knowledge, the amount of energy involved is so tremendous, and the whole scale of operation so gigantic, that it is scarcely to be expected that the electrical condition of the solar regions can ever become intelligible to our comprehension. One thing at least is certain, namely, that the electro-magnetic condition of the earth is very perceptibly influenced by that of the sun. Not only are the so-called magnetic storms frequently, if not always, associated with visible changes in the solar photosphere, but the various inequalities of the earth's magnetism are also known to be due more or less directly to

THE

INDIA RUBBER, GUTTA PERCHA, & TELEGRAPH WORKS COMPANY, LIMITED.

Offices: 106, CANNON STREET, LONDON, E.C.

MANUFACTURERS OF

DYNAMO MACHINES,

INSULATED ELECTRIC LIGHT WIRES AND CABLES,

Lamp Fittings, Switches and Testing Apparatus, Volt and Ampere Meters.

CONTRACTORS FOR THE SUPPLY AND FITTING UP OF

ELECTRIC LIGHT APPARATUS

OF EVERY DESCRIPTION.

INSTALLATIONS FOR CENTRAL STATIONS, SHIPS, HOUSES, OR FACTORIES.

ESTIMATES ON APPLICATION.

Works: SILVERTOWN, LONDON, E.

[See detailed advertisement facing "Notes."

SAMUEL ELLIOTT, Albert Moulding Mills, Newbury.

Manufacturer of all kinds of

Wood Casings for Electro Wires and Cables in Yellow Deal, Pitch Pine, Oak, Mahogany, Walnut, &c., in the best manner, struck clean and sharp.

New Book of Registered Designs, containing numerous Illustrations of Casings and Ornamental Covers.

EVERY LENGTH OF COVER STAMPED WITH TRADE MARK. SPECIALITE: DESIGN AND QUALITY.

GOLD MEDAL, LONDON, 1886. STAR DIPLOMA, LONDON. 1887.

THOMAS BARRACLOUGH & CO., Ltd.

Makers of all the most Improved Machinery for

ELECTRIC WIRE AND STRAND COVERING, LAPPING, TAPING, BRAIDING, &c.,

Also for

STRANDING AND MAKING **CABLES** OF EVERY SIZE AND DESCRIPTION.

Globe Works, Rochdale Road, MANCHESTER.

THE

GÜLCHER (NEW) ELECTRIC LIGHT & POWER CO.,

LIMITED,

BATTERSEA, LONDON, S.W.

Gulcher Globe Lamp.

the sun's influence* ; the secular variation is the only one whose connection with astronomical data still remains to be shown. The changes, however, which take place in the magnetic condition of the earth, important as they are not only in their scientific aspect, but also as they affect the seaman and the telegraphist, do not appeal very powerfully to the popular imagination.

There is, however, one phenomenon, hitherto placed in the same category, which is capable of commanding universal attention. The Aurora, even when seen from these latitudes, has a weird and strange appearance, but as displayed in the Arctic regions it presents one of the grandest spectacles which the eye of man can witness. Dr. SOPHUS TROMHOLT, of Bergen, who recently spent a winter amongst the Laps at Kontokœino, despaired of ever being able to convey an adequate idea of the grandeur of the sight. He speaks of waves of light rolling from time to time over the entire sky into the furthest corner of the heavens. Then would be formed the wonderful corona, of which all Arctic voyagers speak with so much enthusiasm, the "streamers" travelling upwards, sometimes in an arch like a rainbow, sometimes from all parts of the horizon, and meeting in the zenith. From one side of the sky to another a drapery, "woven of light and colour," is wafted. Now here, now there—first one, then two, then several bands, one above another, never at rest, and never the same form ; hither and thither the folds sway with a soft fascinating motion, as from one end to the other waves of light chase each other, overtaking, crossing, and meeting ; while the low intense border is described by Dr. TROMHOLT as displaying the liveliest colours of red and green, the upper one fading into the dark background.

No thoroughly adequate theory of this magnificent and mysterious phenomenon has yet been worked out. Most electricians and physicists have not got beyond the general idea that "electrical discharges in the higher regions of the atmosphere" are the proximate cause, and the facile analogy of the Geissler tube has perhaps tended to check a more exhaustive research. FRANKLIN'S theory is one of the most circumstantial, and has been very generally accepted. He supposed the difference of electric potential between the cold air of the polar regions and the warmer and moister air coming from the tropics to give rise to electrical discharges which take visible shape in the Aurora ; but this explanation obviously leaves a good deal unexplained, and in particular it assumes a much more intimate connection between auroral display and atmospheric electricity than has ever been shown to exist. Moreover, as we shall presently show, it altogether fails to stand the crucial test of spectrum analysis. Recently, however, the subject has been attacked from a new standpoint by Mr. NORMAN LOCKYER, and in a Paper of great importance, read before the Royal Society on January 10, he makes a suggestion which merits, as it will undoubtedly receive, the fullest consideration. Those of our readers who follow the general progress of physical science will not fail to be aware that in the Bakerian Lecture for 1887-8, delivered by Mr. NORMAN LOCKYER, he developed a very remarkable speculation, supported by elaborate and painstaking research, which tended towards a very considerable modification of the Laplacian theory of the evolution of the cosmos. This is not the place to attempt even the briefest summary of this brilliant speculation, but it may be said that it seeks to supplement the nebular hypothesis by attaching much greater importance than hitherto to meteorites. Planetary nebular and variable stars, as well as certain other astronomical phenomena which we cannot stay to mention, are referred to the collision and intersection of meteor swarms. The connection of comets with meteors is already fully established, and it may be said that the general tendency of late years has been towards an increasing recognition of the importance of meteorites in the economy of Nature. It has been calculated by Prof. NEWTON that not less than twenty millions of meteors, each large enough to be visible as a "shooting star," enter our atmosphere *daily* ; and in addition there must be a vast amount of "cosmic dust" too fine to be apparent to the naked eye.

Now it has long been known that the spectrum of the Aurora differs very considerably from the spectrum given by an electric discharge in air under any attainable conditions of temperature and pressure. The Aurora spectrum is, moreover, characterised by a bright line which had not hitherto been identified with any known element. The question was involved in additional obscurity owing to the fact that the recorded observations differed considerably amongst themselves, especially in regard to the exact wave-length of this particular line. As long ago as 1833, however, a suggestion was thrown out by OLMSTED to the effect that some connection might exist between the Aurora and shooting stars, and an examination of the recorded displays of either phenomenon since the beginning of the century exhibit a sufficient number of coincidences to lend some colour to the suggestion. This may be taken to represent the general state of knowledge on the subject when it was taken in hand by Mr. NORMAN LOCKYER. In the Paper which he has just read before the Royal Society, after discussing at considerable length the record of earlier observers, he is able not only to offer suggestions tending to clear up discrepancies, but also to bring new evidence of the most important character in favour of the hypothesis that the light of the Aurora is not of gaseous origin, but is due to electric discharges taking place amidst meteoric dust in the higher regions of the atmosphere. Everyone knows, however, that iron forms one of the most abundant constituents of meteorites, and it will therefore seem strange that there should have been any difficulty upon the above supposition in identifying the spectrum. *But as a matter of fact the Aurora spectrum does not, as a rule, contain the lines of iron.* Mr. LOCKYER'S explanation is sufficiently simple. The Aurora spectrum is produced at such a low temperature that only the more volatile substances are able to reveal their presence. The characteristic bright line he has identified as the remnant of the brightest fluting due to manganese. Now, when iron is raised to incandescence, this manganese line is invariably the first line to appear in the spectrum, and this is the case even with the purest electrolytic iron prepared by Prof. ROBERTS-AUSTEN. In the spectra of the meteorites at low temperatures, not only manganese, but also lead, thallium, carbon, and magnesium are rendered apparent before the iron lines begin to show themselves. Finally Mr. LOCKYER institutes a comparison between the spectrum of the Aurora and a compound spectrum built up of lines belonging to the above-mentioned elements at low temperatures, and in this way he obtains a series of coincidences which can scarcely be accidental.

Mr. LOCKYER is, however, content to remark that "the object of his Paper is mainly to direct further inquiries," and it still remains to be shown how far this theory can account both for the periodicity and geographical distribution of the Aurora, and its apparent connection with solar phenomena.

THE INSULATION RESISTANCE OF ELECTRIC LIGHT INSTALLATIONS.*

BY PROF. A. JAMIESON, F.R.S.E., M.INST.C.E., M.I.E.E.

Insulation Resistance of Land Lines and Submarine Cables.—In the early days of telegraph land lines and of submarine cables, *insulation resistance* was neither definitely specified for nor accurately measured during the various processes of manufacture and of maintenance. A few failures, however (in some cases dearly bought), soon impressed electricians with the necessity for paying more attention to this important quality, and they were not long in demanding from contractors the minimum of insulation resistance which would enable their lines to be worked with success. Not only are careful insulation tests now made during the manufacture of insulators and the erection of the land lines under the British Postal Telegraph Department, but "daily tests" are taken of all the more important lines. The minimum insulation resistance which each insulator should have depends upon the length of the line. For a line of 100 miles long each insulator is expected to give a resistance of 500 megohms, whereas for a line of only 10 miles 50 megohms is considered sufficient. When a line has been erected and put into working order it is usual to fix upon a minimum standard insulation resistance per mile. If the measured value at any time falls below this standard then the line is considered faulty, and steps are taken to remove the fault. The Post Office standard is 200,000 ohms per mile. In the cases of subterranean lines and of submarine cables an even still more rigid and careful system of inspection and of testing is now carried out during the manufacture of the cores and cables. The results are invariably reduced to an insulation resistance per unit of length at a standard temperature. The following extract from the specification of a successfully-made and laid cable will serve to illustrate this:—"The insulation resistance per knot of the gutta-percha core shall not be less, when tested at 75°F., than 300 megohms, fourteen days after manufacture and after two minutes' electrification. If the resistance of *any* portion of the gutta-percha (reduced to 75°F.) at any period of the manufacture fall below the above specified limit, the cable to be rejected." Throughout the whole of the operations of coiling and uncoiling a cable into the shore and ship's tanks, during the laying, and subsequently during its existence, the insulation resistance is periodically measured and tabulated.

Results of Neglecting Insulation Resistance in Electric Lighting.—We have been induced thus to particularise the extreme care and attention which is now considered absolutely necessary in the case of land lines and of submarine cables, because the industry of electric lighting has just passed through a similar experience to that which these industries met with in their earlier days. When the industry of electric lighting was first beginning to take root in this country, electric light engineers pooh-poohed the idea of accurately measuring the insulation resistance of any part of their work, and they invariably turned a deaf ear to the timely warnings of telegraph-engineers and electricians. Experience has, however, taught them, as it did their elder brothers, that good uniform insulation resistance throughout an installation is of immense importance, and that it cannot be obtained without careful attention to details and a rigorous system of testing during manufacture and erection, and also after completion. If an installation is not well insulated throughout, leakage of the current takes place, and consequently waste of power and money; electro-chemical action sets in where damp or liquids are present, and the conductor is thereby eaten through or a short circuit occurs, which for a time stops the whole of the lighting. Discredit thus not only falls upon the contractor, but others are frightened from employing the electric light.

Necessity for Discussing a Standard of Insulation Resistance.—The terms usually employed in regard to the insulation resistance of an electric light installation are, that it shall be "good" or "perfect," according to the fancy of the party purchasing the plant or of his adviser. These terms have, however, no specific meaning, and are therefore very variously interpreted. No doubt the society has had this subject before them in committee when drawing up their set of rules for the "prevention of fire risks;" but the Institution as a whole has never had an opportunity of discussing it, and thereby of impressing its members and the public generally with its importance, and the necessity for observing some minimum standard of insulation resistance. The writer had his attention directed the other day to a communication read before the International Society of Electricians, Paris, in November last, by M. Picou, wherein that gentleman ably analysed this question, and proposed a rule based upon tests of short lengths of cotton-covered insulated wire. He has not had an opportunity, however, of learning the extent and the nature of the discussion upon M. Picou's Paper, and he can only, therefore, place his rule before the members, along with a few other rules, and leave them to form their own opinions, guided by their practical experience.

General Propositions.—The following points will no doubt be readily admitted in regard to insulation resistance of electric lighting installations:—

1. That, owing to the comparatively low resistance of the conductor circuit of ordinary electric light installations on the parallel incandescent system, the minimum standard of insulation resistance does not require to be nearly so high per unit of length as in the case of submarine cables.
2. That it should be directly proportional to the electromotive force of the generator, or difference of potential between the conductor and earth, or between the forward and return conductors.
3. That it should be inversely proportional to the total length of insulated conductor, or to the total current, or to the number of lamps in circuit.
4. That, whatever rules or standards of insulation resistance may be adopted, they should be applied, not only to all the conducting wires, but also to the dynamo, the lamps, and all the fittings, or in other words, to the *whole* circuit.

Rules.—1882 *Set of Rules by Society of Telegraph-Engineers and Electricians.*—In May, 1882, in the first set of "Rules and Regulations for the Prevention of Fire Risks arising from Electric Lighting," issued by the Society of Telegraph-Engineers, no standard of insulation resistance or of minimum leakage is recommended. All that we find there on this head is: "The difficulties that beset the electrical engineer are chiefly internal and invisible, and they can only be effectually guarded against by testing or probing with electric currents;" "All wires used for indoor purposes should be efficiently insulated," &c.; "The insulation of dynamo coils and conductors should be practically perfect;" "The value of frequently testing the apparatus and circuits cannot be too strongly urged," &c.

Five years ago even the writer is not aware that any published rule existed, or that any specification contained any definite rule for the insulation resistance of any part of any electrical installation.

Admiralty Rule.—About 1883 or 1884, however, the Admiralty officials requested that the insulation resistance of the dynamos supplied to them should withstand the test of stroking the free end of a conducting wire (the other end being connected to either pole) over any part of the framing without showing any signs of sparking when the machine was driven at its normal speed. The writer does not know whether they still insert this clause in their specifications, or whether they have modified or improved it; but at best it is only a rough-and-ready test, and gives no indication whatever as to the precise locality of a fault or its value in ohms.

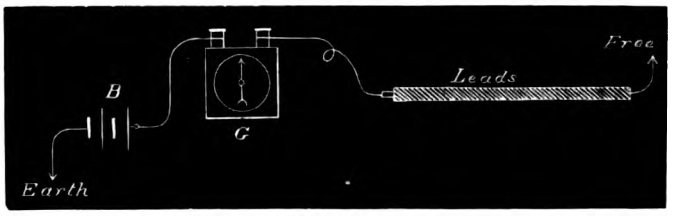

FIG. 1.

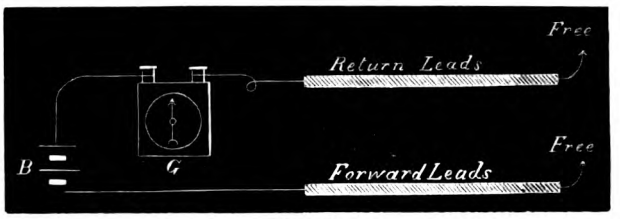

FIG. 2.

Workman's Tests.—The only test applied by contractors when wiring an installation was, and often still is, that of simply inserting an ordinary lineman's detector or galvanometer, G, between a battery, B (of one or two cells), and the leads, with the other end or ends freed, as in Fig. 1. If the galvanometer gives no deflection, or a very small one, then the section is passed as all right.

This is such an exceedingly simple and handy test for workmen that it can scarcely be improved upon, but it gives no precise indication whatever of the resistance in ohms, of the dielectric, or of the fittings. It simply informs the observer whether there is a bad fault or not. He can also find out by it whether the continuity of the conductor is complete, by earthing the further end; and he can also ascertain whether there is a short-circuit or not between any two or more "forward" and "return" leads by connecting up his apparatus as shown in Fig. 2.

* Paper read before the Institution of Electrical Engineers yesterday, January 24, 1889.

Digitized by Google

In 1884 Messrs. Wm. Denny and Brothers' electrician used a small portable magneto-electric machine and sensitive bell — the same as telephone companies employ — instead of the above-mentioned galvanometer and battery. If the bell rang, a fault existed, and its position had to be found out; if it did not, then all was supposed to be right. He, however, in addition to this merely workman's test, applied a more exact test by Wheatstone bridge, and thus obtained the insulation resistance of the whole or of any desired portion of the circuit and the fittings in ohms.

Prof. Jamieson's Rule.—In 1884, whilst testing the electric light wires and fittings of some ships, the writer first drew up this rule, which has been published in the last three editions of Munro and Jamieson's "Pocket-Book of Electrical Rules and Tables." He had previously (since 1881) tested, by Wheatstone bridge, &c., the insulation resistance of a number of land and ship installations, and was rather surprised at the variety and lowness of the dielectric resistance, for his ideas of insulation resistance had been somewhat magnified by seven years' experience with submarine cables. At first, he could not get contractors to come up to his rule, but he was much gratified about this time by the enthusiasm and interest which Messrs. Wm. Denny and Bros.' electrician took in the matter, and by finding such good results in his tests of their ships' lighting leads, which results so far surpassed the demands of his rule that he decided to adhere to it. Since then, he has had much less difficulty, and when care and attention to cleanliness in jointing, to the fixing of wires and fittings, as well as in the manufacture of dynamos, are observed, he has frequently found that the insulation exceeded the demands of his rule, which is as follows:—"A careful insulation resistance test of each circuit, and finally of the whole of the circuits (including all switches and terminals, but not necessarily the lamps) joined up together, should be taken by the method described above,* and not passed unless the resistance is at least equal to ·1 Ω per lamp for every volt employed. The insulation resistance of the dynamo coils should be equally good."

Put into formula shape, the rule is—

$$R_I = k \frac{E}{N_L},$$

where R_I = the total insulation resistance of the whole or any part of the lamp circuits or of the generator in ohms;

k = a constant (·1 Ω = $\frac{1}{10}$ Ω = 100,000 ω) found from actual tests of several well-erected installations;

E = E.M.F. of dynamo or installation in volts;

N_L = number of lamps (16 candle-power) on each circuit or on the whole circuit.

The insulation resistance is therefore here taken to be *directly* proportional to the normal E.M.F. of the dynamo, and *inversely* proportional to the number of 16 candle-power lamps in circuit. The difficulty of ascertaining the precise length of the mains, sub-mains, leads and dynamo windings led the writer to substitute the number of lamps in circuit for what might at first sight appear to be the more exact term in the denominator, viz., the length of conducting wires employed. Although not stated in the above quotation of his rule, the writer usually applies the same test for the resistance or percentage leakage of current between the whole system of forward and return wires, also between the dynamo armature with field-magnet coils in circuit and the frame or body of the machine, as well as between the series and shunt-magnet coils if the dynamo is of the compound or series-shunt type.

The following example and table will make the application of this rule clearer:—

Suppose that we have an installation of 100 lamps of 16 candle-power each, and that the normal difference of potential between the terminals of the dynamo is 100 volts, then the insulation resistance should not be less than

$$R_I = k \frac{E}{N_L}$$
$$= 100{,}000\,\omega \frac{100\,v}{100\,L}$$
$$= 100{,}000\,\omega = ·1\,\Omega.$$

The leakage allowed by this rule in the case of 100-volt lamps using ·64 ampere of current per lamp is

$$C = \frac{E}{R} = \frac{100\,v}{10{,}000{,}000\,\omega} = \frac{1}{100{,}000} \text{ ampere of leakage}$$

for every lamp in circuit. Each lamp, however, requires ·64 ampere; consequently the leakage = $\frac{1}{64\,000}$th part of the total current.

Or, the percentage leakage = $\frac{1}{64\,0}$ = ·0016 per cent.

Since by the above rule the dynamo requires to have the same insulation resistance as the lamp circuit, the insulation resistance of the *whole* circuit, including the dynamo, is half of that given by the formula and tables, and therefore the leakage is double, or $\frac{1}{32\,000}$th part of the total current, or $\frac{1}{32\,0}$ per cent. = ·0032 per cent.

TABLE *of Insulation Resistances required by Jamieson's Rule.*
For 16 *candle-power Lamp Circuits and Dynamos.*

Number of Lamps in Circuit.	50-Volt Lamps.	65-Volt Lamps.	80-Volt Lamps.	100-Volt Lamps.	110-Volt Lamps.
	Ohms.	Ohms.	Ohms.	Ohms.	Ohms.
1	5,000,000	6,500,000	8,000,000	10,000,000	11,000,000

1,000	5,000	6,500	8,000	10,000	11,000

Phœnix Fire Office Rules.—In May, 1888, in the thirteenth edition of the Phœnix Fire Office Rules, Mr. Heaphy recommends that "in any electric light installation in which the current is continuous, and has an electromotive force of 200 volts or under, the insulation resistance over the whole circuit inside any buildings should never run below 10,000 ohms. . . . With currents of 1,000 volts the insulation resistance should never drop below 50,000 ohms, no matter how wet the weather may be. For alternate currents the minimum insulation resistance should be twice the above number of ohms respectively."

In November, 1888, in the fourteenth edition, Mr. Heaphy is more precise, and he has added a table based upon similar proportions to the writer's rule.* His Rule No. 27 reads as follows:—

"In any electric light installation in which the current is continuous, and has an electromotive force of 200 volts or under, the insulation resistance over the whole installation should not be below the following:—

"Installations of	25 lights	.....	500,000 ohms.
,,	50 ,,	.....	250,000 ,,
,,	100 ,,	.....	125,000 ,,
,,	500 ,,	.....	25,000 ,,
,,	1,000 ,,	.....	12,500 ,,

When the lights are proportionate between the above numbers, then the insulation resistance should be correspondingly proportionate. The insulation resistance of separate circuits of the installation should also be taken, and should be in accordance with the above table. For alternate currents the minimum insulation resistance should be twice the above number of ohms respectively."

Objections to Phœnix Rule.—The following objections may be offered in regard to this last rule:—

1. It ties down a contractor to one and the same insulation resistance, whether the E.M.F. of the installation lies *anywhere* below 200 volts. Surely a 50-volt installation requires but half the insulation resistance of a 100-volt one, and but one-fourth that of one with 200 volts.

2. It is somewhat doubtful (owing to a previous note to Rule No. 20) whether the words "over the whole installation" include the dynamo as well as all the wires, fittings, and lamps.

3. No distinction is made between circuits with one, or two, or more lamps in each parallel.

4. Arc lamps of 2,000 candle-power or more in parallel and large incandescent lamps of 500 candle-power or more, which require strong currents, come under the same general words, "any electric light installation in which the current is continuous," just as much as small incandescent lamps of, say, 5 candle-power, which require only a fraction of an ampere.

A question naturally arises here for discussion—Should not the insulation resistance in such extreme cases bear some definite proportion to the current?

* See Munro and Jamieson's "Pocket Book of Electrical Rules and Tables," p. 179, at foot. This rule applies only to the dynamos, leads, and fittings for incandescent lamps arranged on the single parallel system. Should the lamps be arranged in parallels, with two or three or more lamps in series in each parallel, they count as but one for each parallel.

* It will be observed that the above table corresponds identically with the writer's rule for an E.M.F. of 125 volts; *e.g.*, take 100 lamps: then

$$R_I = k \frac{E}{N_L} = 100{,}000\,\omega \frac{125\,v}{100\,L} = 125{,}000 \text{ ohms};$$

and so on in proportion to the number of lamps.—A. J.

Westminster Fire Office Rule.—In 1888 the Westminster Fire Office issued a set of rules for guiding their officers in regard to electric light installations, in which they demand that the insulation resistance shall in no case be less than 150,000,000 ohms per mile ! ! ! Surely they have been blindly making extracts from a submarine cable specification ! No contractor could be expected, under ordinary circumstances, to complete his work (including dynamo and fittings) to such a high standard.

M. Picou's Rule.—On November 7th, 1888, M. Picou communicated his rule to the International Society of Electricians, Paris. Using the same symbols as in the writer's rule, it is—

$$R_I = k \frac{E}{C},$$

where R_I = the total insulation resistance of the circuit in ohms ;
k = a constant (500) found by experiments with short lengths of wire covered with three layers of cotton wound in reverse layers and pressed between metal plates.
E = maximum E.M.F. of the generator in volts ;
C = total current generated or passing through circuits in amperes ;
$\frac{E}{C}$ = the resistance in ohms of the whole circuit when the installation is in full working order.

The differences between M. Picou's rule and the writer's lie in the different values given to the constant k, and in the substitution by M Picou of the total current, C, for the total number of lamps, N_L, in the writer's rule. There is no doubt an advantage in thus substituting C for N , since the constant k thereby expresses directly the number of times the insulation resistance is of the apparent working resistance, $\frac{E}{C}$. And its reciprocal, the proportion which the leakage current bears to the total current. For, let c = the leakage current, and adopting the same symbols as above for the other terms, then

$$c = \frac{E}{R} = \frac{E}{k\frac{E}{C}} = \frac{C}{k},$$

$$\therefore \frac{1}{k} = \frac{c}{C} = \frac{\text{leakage current}}{\text{total current}}.$$

We, however, consider that M. Picou's constant, 500, is by far too low to ensure good and lasting work. By it, a circuit of 1,000 lamps of 16 candle-power each, requiring 100 volts and ·64 ampere each, the total insulation resistance of the circuit would only need to be 78·1 ohms, instead of 10,000 ohms by the author's rule (or 5,000 ohms if the dynamo be included).

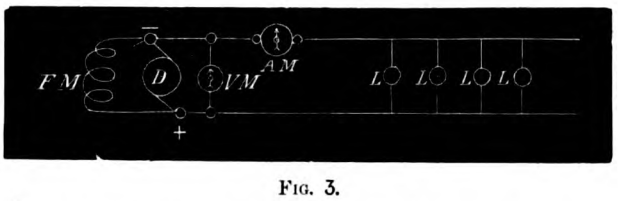

Fig. 3.

The Society of Telegraph-Engineers and Electricians' Last Rule.—In April, 1888, this society issued its second pamphlet of "Rules and Regulations for the Prevention of Fire Risks," and Rule 16 states that "the insulation of a system of distribution should be such that the greatest leakage from any conductor to earth (and in the case of parallel working from one conductor to the other when all branches are switched on, but lamps, motors, &c., removed) does not exceed $\frac{1}{5000}$th part of the total current intended for the supply of said lamps, motors, &c. ; the test being made at the usual working electromotive force." This rule includes all kinds and systems of electrical installations, and it is very neatly and concisely expressed. Some persons have, however, a difficulty in understanding how the $\frac{1}{5000}$th part of the total current is to be tested for or ascertained, and others do not see exactly how the test is to be applied to different parts of the circuits at the usual working E.M.F. *before* the installation is put into working order.

If the rule had also been put into the following form, with a table giving the insulation resistances required for a few of the more common electromotive forces and currents (or number of lamps), it would no doubt have recommended itself more readily to those unaccustomed to deal with the form of expression used in the rule. Using the same symbols as before, we have—

$$\frac{1}{5,000} C = c = \frac{E}{R_I}$$

$$\therefore R_I = 5,000 \frac{E}{C} = k \frac{E}{C},$$

which is the form of expression used before, and most easily applied. This gives a constant ten times as great as M. Picou's, and about one-tenth that of the writer's rule. Which of these constants is most in accordance with good practice ?

Table *of Insulation Resistances required by the Society of Telegraph-Engineers and Electricians' Last Rule,* viz., the leakage of any part of an installation not to exceed* $\frac{1}{5000}$*th of total current supplying that part ; or,* $R_I = 5,000$ E/C.

Number of Amperes in Circuit.	For 50-Volt Lamps.	For 65-Volt Lamps.	For 80-Volt Lamps.	For 100-Volt Lamps.	For 110-Volt Lamps.
	Ohms.	Ohms.	Ohms.	Ohms.	Ohms.
1	250,000	325,000	400,000	500,000	550,000
10	25,000	32,500	40,000	50,000	55,000
20	12,500	16,250	20,000	25,000	27,500
40	6,250	8,125	10,000	12,500	13,750
50	5,000	6,500	8,000	10,000	11,000
100	2,500	3,250	4,000	5,000	5,500
150	1,666	2,166	2,666	3,333	3,666
200	1,250	1,625	2,000	2,500	2,750
300	833	1,083	1,333	1,666	1,833
400	625	812	1,000	1,250	1,375
500	500	650	800	1,000	1,100
1,000	250	325	400	500	550

* If we include the dynamo as well as the whole of the lamps, motors, &c., will the insulation resistance of the *whole* installation be half the above figures ?

Different Tests.—The ordinary Wheatstone bridge test is the handiest and easiest method of ascertaining the actual resistance in ohms of the conductors as well as of the insulation resistance. Should the insulation, however, be too high for the battery power and the galvanometer, then the direct deflection substitution method may be adopted. These tests are so fully described in every book on testing, and are, besides, so well known, that there is no need to explain them here. The battery power need only be a few Leclanché cells (10 or 12 at most) if the galvanometer used is of the sensitive-mirror Thomson type.

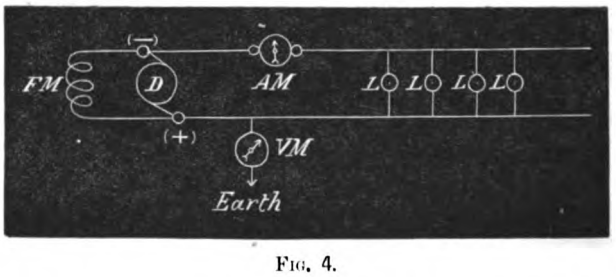

Fig. 4.

When the installation has been completed, then the whole of the results may be obtained by means of ordinary ampere and volt meters.

First, join up the circuit as follows, in Fig. 3. Work the installation at its normal power and observe the total current, C, by the ampere-meter, A M, and the difference of potential E, by the voltmeter, V M. This gives us $\frac{E}{C}$.

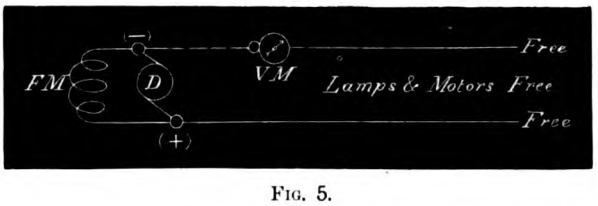

Fig. 5.

Second, join up the voltmeter as in Fig. 4, with one side to earth, having previously ascertained its resistance, r, ohms. Also note C on the ampere-meter, and see that it is the same as before.

If any leakage to earth exists in the dynamo or in any part of the circuit, a deflection on the voltmeter, V M, will be produced corresponding to the leakage current c passing through it, and is represented by e volts difference of potential between its terminals.

Then, $\frac{e}{r} = c$, the total leakage current.

But $\frac{C}{c} = k$, the actual constant or coefficient of the insulation resistance of the system.

Digitized by Google

Then, if this value is greater than k, our standard constant, the installation may be considered all right as far as insulation resistance is concerned. Of course this does not inform us if any leakage is taking place between the forward and the return system of wires, or between the shunt and the series windings of the dynamo.

To ascertain the former of these, disconnect all the lamps and insert the voltmeter first in the forward lead, and secondly in the return lead, as in Fig. 5, and note if we get any leakage curcent, c, when the dynamo is run at its normal speed. In regard to leakage between the shunt and series windings of the dynamo magnets, recourse must be had to the Wheatstone bridge test.*

No doubt some of the members will suggest other practical tests, as well as give their experiences of how the insulation resistance of installations with which they happen to be intimately acquainted compare with the various rules herein mentioned, as well as how they stood the test of time and wear and tear of everyday work. What is chiefly wanted is to ascertain the minimum standard of insulation resistance compatible with good honest work and ordinary careful usage.

P.S.—Since correcting the proof-sheets of this Paper the writer thought that it might be interesting and instructive if he obtained the insulation resistance of an installation that had been working for some years, because members and others might say that some of the foregoing rules were all very well for *new* work, but were quite inapplicable to *old* work. He accordingly went to-day (January 16th, 1889) to Messrs. Graham's large East India offices and warehouses in Cathedral-street, Glasgow, with his testing apparatus, and took careful tests of the insulation resistance of the whole circuit, with the results shown in the following table :—

Original date of fitting up installation	1881-82
Date on which most of the wiring was renewed	1883
Date of test (day wet—Glasgow weather)	Jan. 16th, 1889
Total number of lamps in circuit of 16 candle-power each	281
E.M.F. at brushes of dynamo in volts	108
Current total from dynamo for all lamps, in amperes	(*about*) 160
Insulation resistance of dynamo armature and magnet coils alone, in ohms	40,000
Insulation resistance of the *whole* circuit, including the dynamo, *all* leads, switches, cut-outs, and lamps, in ohms	21,400
Insulation resistance to pass Jamieson's rule, including *dynamo* as well as the *whole* lamp circuit, in ohms	19,217
Insulation resistance to pass Society of Telegraph-Engineers and Electricians' rule (if their constant includes *dynamo* as well as the *whole* lamp circuit), in ohms	3,375

This old installation (the oldest large incandescent light one in Scotland), which has been in full daily working order for over five years (since the wiring was renewed), when tested without warning or any special preparation, and on a very damp day, gave a better insulation resistance than that demanded by the writer's rule, and over six times that required by the Society of Telegraph-Engineers' rule (taking it in its broadest sense).

It is worth mentioning that the President, Sir William Thomson, has taken a special interest in this installation from its very commencement. In 1881, when so few electricians knew practically how incandescent lighting should be carried out, and when the Messrs. Graham were erecting their large new premises, they consulted Sir William Thomson as to whether or not they could rely upon the electric light. Upon his recommendation they fitted their premises throughout with the electric light, without introducing gas-burners into any of their offices and warehouses. The actual carrying out of the present wiring of the building has been entirely done by one of the writer's students, who has had charge of the installation for the last six years The Messrs. Graham have been so pleased with the care and attention which he displayed that they have sent him to their new premises which they are at present erecting in Oporto, Portugal, to superintend the building and put up an electric light installation there.

The dynamo which the writer tested, and which gave a total insulation resistance of 40,000 ω, against framing and dead earth, is a Manchester shunt-wound machine by Messrs. Mather and Platt, put down about two years ago to replace the direct lighting of the building by three of the oldest shunt-wound dynamos in existence. These three machines are now employed in charging accumulators which serve to feed the lamps used in the darker parts of the building during the daytime. The writer tested the insulation resistance of one of these old machines, and found that it gave for armature and shunt coils just over 10,000 ohms, as against the frame of the machine.

In addition to the above tests, that indicated by Fig. 4 was applied, and no perceptible leakage current was observable on the voltmeter, even although the sensitive coil, which reads to less than a volt, was inserted.

The writer might give the results of several new installations which have surpassed his rule, and which therefore far exceeded the demands of the society's rule. He therefore thinks that the constant of the latter might be raised from 5,000 to 10,000 with perfect fairness, and with beneficial results to the electric lighting industry as a whole.

* For other tests when the installation is at work, *see* Munro and Jamieson's "Electrical Rules and Tables," Fifth Edition, pp. 215, 216.

LEGAL INTELLIGENCE.

In re Gaulard and Gibbs' Patent.

COURT OF APPEAL.—THURSDAY, JANUARY 17.

Mr. ASTON proceeded to deal with the evidence of Dr. Hopkinson. With reference to the question of anticipation Dr. Hopkinson was of opinion that the working of secondary generators in the way adopted by Messrs. Gaulard and Gibbs was an advantage, and said he did not know of any system that was in use prior to 1882 where secondary generators were worked in that way on a main circuit. He (Mr. Aston) was not aware that that evidence had been contradicted. The attention of Dr. Hopkinson was then called to particular cases where similar appliances had been adopted, the Jablochkoff system being first taken. Jablochkoff had in view, as he said in his title, a new process of producing and dividing the electric light. In 1878, though the general opinion was that it was impossible to have more than one light supplied by one machine, that notion of course had been proved to be entirely erroneous ; but at that time it was the notion which prevailed in many minds, and the object of these patents was to employ divided currents for small lights. There was, said Dr. Hopkinson, nothing in Jablochkoff's specification to show that it was intended to have a very long main wire and to have high tension on the main wire, and there was nothing in the Jablochkoff specification which would lead the minds of any person to employ the Gaulard and Gibbs system consisting of the three electrical elements which were the special subject of their patent. Jablochkoff's intention evidently was to divide the electric light and to obtain a high tension suitable to the lamp which he intended to use. Dr. Hopkinson's attention was then called to the Du Moncel system, which was dated in the same year. Dr. Hopkinson thought the system was in no way an anticipation of Messrs. Gaulard and Gibbs, and he gave similar evidence with reference to Bright's specification. With regard to Johnson's specification, Dr. Hopkinson said he thought it described a very inefficient induction coil which would be less useful than a Ruhmkorff, and it made no reference to the necessity for high tension. Dr. Hopkinson's attention was then called to the specification of Edwards and Normandy, and when asked if it was anticipatory of the specification of Gaulard and Gibbs he also gave a negative answer. There was no instance of any one of these systems having been brought into practical use. Their lordships might take it that the secondary generator described in Gaulard and Gibbs's patent was a known thing ; but no person had thought of sending currents of high tension through a long main wire by the aid of these secondary generators. If they had done so he would have had no case. Whether that would be subject matter or not it was for their lordships to consider. The question was—were these three elements used for the first time to secure that which Sir William Thomson called an important development? Having read the evidence of Dr. Hopkinson *in extenso*, Mr. Aston said he did not propose to deal in the same way with the evidence of the witnesses who followed Mr. Swinburne, Prof. Adams, Prof. Forbes, and Mr. Gibbs, who, he maintained, substantially confirmed Dr. Hopkinson, though it might be necessary to refer to some of their statements.

Sir HORACE DAVEY said he would have to refer to the greater part, practically the whole, of Mr. Swinburne's examination.

Mr. ASTON said in that case he would read the evidence, which he proceeded to do. He afterwards proceeded to deal with the evidence of Prof. Adams, who spoke of making use of alternating dynamo machines with a current of high tension to work the secondary generator as a novelty.

LORD JUSTICE COTTON : Is that a novelty ?

Mr. ASTON : Yes, my lord ; and so it was. There was not in any one of these prior machines an alternating current of high tension working secondary generators with divided cores.

LORD JUSTICE COTTON : That is not what the witness said. You introduce divided cores. He did not do that.

Mr. ASTON said the witness spoke of working the second generator, and the divided core in the generator was part of Gaulard and Gibbs's system. Witness was further examined as to the Ruhmkorff coils and intermittent currents.

LORD JUSTICE COTTON : As I understand the term, intermittent means a current always in the same direction, but from time to time very rapidly broken (I do not know whether that is very material), and an alternating current is where the current goes round a different way, but returns to the machine.

Mr. ASTON : From terminal to terminal without being interrupted.

LORD JUSTICE COTTON : I understand that is the construction of the two terms ?

Mr. ASTON : That is the construction put upon them ordinarily. That is not denied.

Mr. MOULTON proceeded to read the cross-examination of the witness.

Mr. ASTON next referred to the evidence of Mr. Gibbs, the co-patentee, and was followed by

Mr. MOULTON, who proceeded to deal with the evidence for the defendants, the first and principal witness being Sir William Thomson.

A generating machine was then exhibited to the Court for the purpose of illustrating the Jablochkoff arrangement.

Digitized by Google

LORD JUSTICE COTTON asked what was the action of the current?

Mr. MOULTON said he might almost call it sympathetic. A current passing in one direction generated a current in the opposite direction. It was the most extraordinary thing in the world. Induction coils were placed in the circuit of the machine, and the lamps were connected to the secondary circuits. Jablochkoff contemplated a number of lights being put on the circuit, and by varying the arrangement and dimensions of the bobbins he could give the requisite tensions to his currents to produce lights of very different intensities. Sir William Thomson was of opinion that in 1877 electricians would have been able from this specification to have arranged a system of distribution of electricity, but, as a matter of fact, it was not done at that time.

Mr. MOULTON said that Sir William, in answer to further questions, said that all that was done in Paris was in the form of arc lamps. Electricians had the key of the secret in their own hands, but there was not at that time the demand for doing the thing. It was early found that arc lighting could be done by putting a number of arc lights in series in connection with secondary generators or induction coils.

The Court adjourned until the following day.

FRIDAY, JANUARY 18.

Mr. ASTON, continuing his speech, pointed out that the witnesses for the patentees had said that the various inventions which were relied upon in all cases had something introduced which required to be removed or altered, or modified, or some addition was required to be made to every one of the prior specifications in order to make them fit Gaulard and Gibbs's invention. On the other hand, there was the evidence of Sir William Thomson, who said that the method of constructing induction coils either increasing the intensity by causing the secondary wire to offer a greater resistance than the primary, or by causing the secondary to offer a less resistance than the primary, in which case there was a less intensity than there was in the primary, was perfectly well known. The method of winding was perfectly well known. The quantity of wire that there ought to be on the bobbins was perfectly well known, as he (Mr. Aston) admitted in the opening of the case in the Court below. The secondary generator, according to Sir William Thomson, was well known, not only to scientific persons, but to scientific instrument makers. But no question was put to Sir William Thomson as to the combination of the three elements, which were the main feature of Gaulard and Gibbs's invention, though Sir William admitted that their secondary generator was of special construction, though not in any shape novel. He then proceeded to read the cross-examination of Sir Wm. Thomson, with a view to showing the state of public knowledge at that time, and he contended that the witnesses for the patentees were practically uncontradicted, and that there was no evidence of anticipation before the Court.

Mr. MOULTON then read the re-examination of the witness, and continued with the examination of Dr. Fleming.

LORD JUSTICE COTTON: Do you claim the use of secondary generators like those described?

Mr. ASTON: Yes.

LORD JUSTICE COTTON: Then I think I ought to ask you what is the peculiarity, what is the speciality of those generators?

Mr. ASTON: It is a generator which of necessity has a divided core—nothing else will do—a generator which is capable of being modified so as to give the requisite tension according to the work that has to be done. The withdrawing of the core points in that direction. If your lordship asks me if I claim for the withdrawing of the core, I do not, but I claim a secondary generator.

LORD JUSTICE COTTON: I understand you do not claim anything in the generator?

Mr. ASTON: Nothing.

LORD JUSTICE COTTON: But you say there must be a special kind of generator to make up the combinations which you claim?

Mr. ASTON: Yes.

LORD JUSTICE COTTON: I was rather led to ask the question, because you thought that originally you could claim the secondary generator described as your special invention.

Mr. ASTON: The patentees *did* think so.

LORD JUSTICE COTTON: You claim the divided core?

Mr. ASTON: And bobbins so arranged as to enable the generator to do the work required.

LORD JUSTICE LOPES: I understood you to say these were two essential elements?

Mr. ASTON: That is the case, my lord.

LORD JUSTICE COTTON: Would not that be the case with all secondary generators? The coils could be modified by convolutions more or fewer.

Mr. ASTON: In this case the variation is more easily provided for.

LORD JUSTICE COTTON: You mean to say by the number of these bobbins that are separated from one another.

Mr. ASTON: Yes, my lord, and it is to be borne in mind that you can arrange the bobbins in series.

LORD JUSTICE LINDLEY: I do not see why your induction coil may not be any induction coil which answers the purpose.

Mr. ASTON: Any induction coil which answers the purpose so long as it has a divided core and is capable of modification.

LORD JUSTICE LINDLEY: They all have the divided core now.

Mr. ASTON: No, my lord; out of the six or seven specifications that are relied on, three or four have the solid cores.

LORD JUSTICE LINDLEY: Sir William Thomson says that anybody making an induction coil now would make a wire core.

Mr. ASTON: I think they would, now we have told them for the first time what would answer, namely, using cores that will not give Foucault currents. Once you have a secondary generator which is capable of being so modified as to do modified work, that will be of the class which we require.

LORD JUSTICE LOPES: I understood the evidence to be that the old Ruhmkorff coil would not do.

Mr. ASTON: A solid core would not do.

Sir HORACE DAVEY: The Ruhmkorff coil never had a solid core.

Mr. ASTON: My claim is for an alternating dynamo sending currents of high tension through a long main wire, and I stand or fall by that. It was the entire combination which is a novelty. There is nothing that I or my witnesses said in the Court below which is contrary to that construction.

LORD JUSTICE LINDLEY: I understand one of the difficulties is that the proportions between the two wires are not disclosed. The sizes are but not the lengths, and we want to know the number of convolutions as well.

LORD JUSTICE LOPES: Must not that depend upon the use to which you are going to put the apparatus?

Mr. ASTON said that the number of convolutions would vary with the number of the lamps. Details of this kind could not be defined in a specification. Of course, when the attention of Sir William Thomson was directed to picking holes in the specification, he said these details were not there, but he (Mr. Aston) should contend that they were not details of a kind which would invalidate the patent. He now approached a part of the case to which it would be necessary for him to refer with great care. Assuming that it was true that the problem that Messrs. Gaulard and Gibbs set out in their specification had been referred to in prior specifications, he should contend that the object was different. In all these prior specifications (which he was going to examine *seriatim*) the object was different. And that it was likely to be different arose from this fact, that the lamps which were used in 1878 and 1879 were lamps for which it was not necessary to have very high-tension alternating currents that could be sub-divided so that the light of one lamp in the series should not, by being extinguished, interrupt the continuity of operation of the series. Sir William Thomson knew every one of the electrical facts disclosed in the prior specifications. He had himself endeavoured to solve the problem of the distribution of electricity over long distances, and he knew that there must be high tension, and if he had had the wit to see that there must be high-tension alternating currents he might have solved the problem. But his mind was upon direct currents. He knew all about induction apparatus; there was nothing new in that. Had he given a single instance where an induction coil had ever been used prior to this specification? Sir William Thomson was on the verge of the discovery. He had the ideas; he knew you must not introduce into a building electricity of such a tension as to be dangerous, and he thought to provide what was necessary by a storage battery. And a grand thing that storage battery undoubtedly was; it was beautiful, and no wonder that Sir William Thomson went breast high in hope that the problem was solved. But he had the wrong high tension. If he had put the induction coil in the place of the storage battery he would have solved the problem. Mr. Aston then proceeded to deal with the question of the validity of specifications generally, and quoted decisions of Lord Westbury and Sir George Jessel upon that point.

The Court adjourned until the next day.

SATURDAY, JANUARY 19.

Mr. ASTON, continuing his address, proceeded to refer to the specification of Edwards and Normandy, which, from the point of view of anticipation, no doubt came near to the specification of Gaulard and Gibbs. It was a provisional specification, which apparently was never completed. That fact, though not in itself conclusive, went, he thought, a long way. The specification stated the object of the invention was the improvement of electric lighting, so that the current of electricity obtained from magneto-electric machines or other apparatus might be made to produce as many electric lights as might be required, and in any desired positions or localities, and such separate lights might be extinguished or regulated without difficulty. That in the first place was a different object from that which Messrs. Gaulard and Gibbs had in view. Then the specification continued: "We take one or more magneto-electric machines of any of the well-known kinds." There appeared to be no limitation as to the kind of machine, or as to the kind of current which should be employed. The machine, the specification went on to say, was to be situated in any convenient central position in relation to the lights which were to be produced, and might be driven by steam or any convenient power, "so that a very rapidly intermittent current of electricity of any desired magnitude is produced from it, is conveyed along a metallic wire properly insulated in the usual way, and passes through or near every station or position where it is desired that a light should be produced." The witnesses for the patentees all said that an intermittent current had a particular meaning; it meant a current which was sent intermittently from the originator of electricity, was continuous as regards direction, and discontinuous as regarded supply. Dr. Hopkinson also gave evidence to the same effect, and that, said the patentees, was the fair reading of the specification of Edwards and Normandy. Sir William Thomson said that an alternating current was intermittent. Of course it was, but it was not intermittent as regarded the sending; it was not a current which was sent intermittently from the machine in one direction, being assisted by a make and break apparatus. He submitted that Sir William Thomson put a strained construction upon the words when he said that an alternating current might also in a sense be intermittent. That was impossible. The next clause in the specification was very important. "The circuit of the current"—that was the intermittent current—"is completed either by bringing the wire back to the machine at the generating station or connecting it to earth." Nobody had said that

Digitized by Google

Gaulard and Gibbs had ever contemplated an alternating current connecting with the earth. The current they used was one which swept round from terminal to terminal. Whatever current might have been contemplated in Edwards and Normandy's specification, it was clearly not the alternating current of Gaulard and Gibbs. The same idea pervaded the whole of the specification, in which (if he were right) there was no direction as to the use of an alternating current at all. There was another statement which overrode the whole. "A sufficiently powerful galvanic battery may be used instead of a machine"; but though the battery would give an intermittent current with a make and break arrangement, it would not give the alternating current which Gaulard and Gibbs described Edwards and Normandy started by saying that any magneto-electric machine would do. Sir William Thomson said, applying his own knowledge, that of course people would select machines giving alternating currents; but that did not appear upon the specification, and Sir William Thomson, in going through the specification, ignored the direction to use intermittent currents rapidly produced.

LORD JUSTICE LINDLEY, in reference to the evidence of Sir William Thomson, said he did not know the difference between a dynamo and an electro-magnetic machine. Harrison's patent did not speak of dynamos, but of an electro-magnetic machine. He wished to know whether a dynamo sent a continuous current, and a magneto-electric machine an alternating current.

Mr. ASTON said a magneto-electric machine was a machine which had a permanent magnet.

Sir HORACE DAVEY: A dynamo has a magnet created by electricity.

LORD JUSTICE LINDLEY: They both send alternating currents, do they?

Mr. ASTON: Yes; but you might have a magneto-electric machine that sent a continuous current, and at this time the Siemens and the Gramme machines—which were being introduced as being very important machines—had the continuous current interrupted. As regards the specification of Edwards and Normandy, Dr. Hopkinson was asked this question: "Do you think that Edwards and Normandy's is a system which would lead anybody to employ the system of Gaulard and Gibbs?" To this the answer was "No." "Would it teach them what Gaulard and Gibbs's specification teaches them?"—"No." Mr. Aston then said he would refer, lastly, to the specification of Imray. Imray began with a low tension from a battery. The tension was raised by means of an induction coil, and high tension was used to go along the wire, but it was not the high tension produced from an alternating machine or of an alternating character. There was nothing about high tension in the specification of Edwards and Normandy, though if the current was sent over long distances, say 50 miles, there must be high tension. If the problem which Messrs. Gaulard and Gibbs had in view had been solved in the specification of Imray, he submitted that the matter would have been heard of in the Electrical Congress at Paris in 1881. There was no description in Imray of the Gaulard and Gibbs process. Mr. Aston concluded by appealing to the Court on behalf of a system comprising the following elements:—1, A high-tension alternating dynamo; 2, transmitting currents along a main wire at high tension; and 3, a main wire having at intervals local installations obtained by means of induction apparatus.

Mr. GRAHAM also addressed the Court, and claimed for the invention of Messrs. Gaulard and Gibbs four special features:—1, divided and movable core; 2, divided secondary arrangement (which could be coupled in series or in quantity); 3, high tension in the primary and low tension in the secondary; and 4, the absence of the make and break. Though the patentees could not claim the invention of these special features, they claimed the combination as a new combination, amounting in reality to a new invention. The way in which the petitioner framed his argument in the Court below was this: he minimised these special features, and he minimised them to such an extent that the learned judge was led to believe there was nothing in them. But speciality was the essence of the patent, though in itself it might be of very little value. Be that as it might, the patentees desired to keep it. Mr. Graham dwelt upon the importance of the divided core, and said that the state of electrical knowledge at the date of Gaulard and Gibbs's specification was such, that if any practical electrician had been told that what was claimed by the combination in the specification was possible, he would have laughed at the idea as an absurdity. The divided core prevented heating, and lamination also ensured economy of working. With regard to the Jablochkoff specification, he contended that it could not in any sense be said to have been an anticipation. The specification of Edwards and Normandy he described as a tissue of electrical absurdities and misdirections. Deprez no doubt provided for the transmission of electrical energy, because he said it was possible to heat a platinum wire at a distance of several hundred thousand yards by means of a battery consisting of two Bunsen elements; but he contended that could not be taken as evidence of Deprez's knowledge that electrical energy so distributed could be used for purposes of electrical lighting. Mr. Graham concluded by saying that if the patent was valueless, as was alleged, he could not see what object there was in revoking it.

LORD JUSTICE COTTON: We have not got to consider that; we have only to consider whether the patent is good or bad.

SIR HORACE DAVEY: My friend is trying to save his patent by minimising it.

The Court adjourned until Monday.

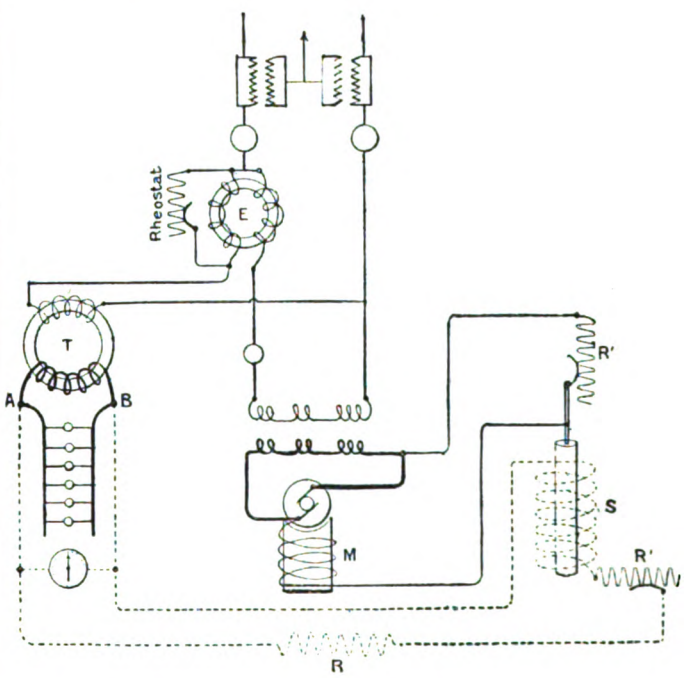
(To be continued.)

Russo-China Telegraph.—We understand that some French engineers have been despatched to Russia with a view to the laying of a telegraph line from Russia to China across Siberia.

THE ELECTRIC LIGHTING OF DIEULEFIT AND VALREAS.*

A central lighting station containing several features of interest was inaugurated near the town of Dieulefit on the 25th December last. The idea of lighting the towns of Dieulefit and Valréas from the same station was due to M. Charles Noyer, mayor of Dieulefit, and the execution of the project was entrusted to MM. Lombard Gerire et Cie., of Lyons.

The central station is situated at Béconne, which is 5 kilometres from Dieulefit and 14 kilometres from Valréas. The motive-power is obtained from the Lez, a short canal, taking the water to a 3,000,000-gallon reservoir. A fall of 25 metres is utilised, so that this reservoir represents a reserve of about 1,200 horse-power-hours, or nearly 800 electrical horse-power-hours available for lighting. An iron pipe 80 centimetres in diameter brings the water from the reservoir to the two 50 horse-power turbines, which run at 180 revolutions a minute. Each of these turbines drives an alternating-current Zipernowsky dynamo, giving 12 amperes and 2,000 volts, and its exciter, a shunt-wound machine giving 30 amperes and 80 volts. Each town is served by a distinct set of plant comprising the turbine, alternator and exciter. The reserve consists of a third alternator, which will shortly have a third turbine to drive it. The speed of the turbines is kept constant by a Bouvier hydraulic governor. This mechanical governing is, however, insufficient to keep the difference of potential constant at the lamp terminals, since the line resistance is 14 or 15 ohms, which, with a current of 12 amperes, means a loss on the leads of 180 volts. An ingenious method of regulation is, therefore, resorted to.



The lamps lighting the station are run off a special transformer, T, the primary coil of which is in parallel with the line. One coil of the "equalising-transformer" E, it will be observed, forms part of the main circuit; while the other coil, which is shunted by an adjustable resistance, is in series with the primary of T. The result of this arrangement, it is obvious, is to cause a diminution of current in the primary of T whenever the current in the main circuit increases, owing to the increase in the back E.M.F. of the shunted coil, caused by the increased mutual induction of the main line and shunted coils. In order, therefore, that the E.M.F. at the terminals A B should remain constant, the difference of potential at the terminals of the dynamo should increase as a function of the output. By suitably arranging the transformer T, the "equaliser" E and the resistance of the rheostat, it is possible between the ordinary limits of working to compensate for the losses on the line by merely keeping the difference of potential between A and B constant. With this object a circuit is interposed between A and B, consisting of a resistance, R, a solenoid, S, and an adjustable resistance, R'. The core of this solenoid is a thin sheet of soft iron, and its motion alters the resistance of the shunt of the exciter M. If the difference of potential between A and B tends to diminish, the resistance of the field-magnet coils of the exciter M is decreased, and the exciting current is consequently

* Abstracted from *l'Electricien*, 12th January.

Digitized by Google

augmented, and *vice versâ*. By this means the lamps in each town are kept at their proper E.M.F. whatever the output of the machines may be.

The main conductors are of silicium bronze, uninsulated and run overhead. The Dieulefit line is of 3·2 millimetres wire, the line to Valréas being of greater size, to equalise the resistance. The station is in telephonic communication with either town. The transformers have all a 1,500 watt capacity, and are enclosed in zinc cases fixed to brackets on the walls; their coefficient of transformation is 18, and the E.M.F. at the terminals of the primary being 1,750 volts, the difference of potential at the lamps is 95 volts. At Dieulefit, which is a long straggling town, and where the distance between the first and last lamp is 3 kilometres, the secondaries are all coupled together, with a view to equalise the distribution. At Valréas, on the other hand, which is almost a perfect circle, the secondaries have been arranged in distinct groups, each fed by three transformers. Up to the present everything has been running very well.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *January 12th*, 1889.

I presume that electrical circles in England are well advised by this time of the sensational exposure which has just been made of the affairs of the Electric Sugar Refining Company, which has its head quarters in this city, and in which a great deal of solid British gold has been invested. If I mistake not you have already given some little space to the affairs of this company, and accurately characterised its remarkable pretensions, but perhaps a few words from this end of the line will not be without interest. The company was formed to develope and utilise a secret process for refining sugar by the use of electricity, and it now appears, as has always been suspected, that electricity has as little to do with the matter as it has with the production of coffee. This process, such as it was, owed its authorship to a chemist by the name of Freund, who, it now appears, was by no means too reputable a person, and who made various efforts in other cities to interest capital before he settled down in New York. The scheme was first brought to the attention of the sugar trade some four years ago, when Freund startled the refiners by announcing that he could take the worst raw sugar and turn it into the best refined at a cost of about 80 cents. a ton. Just how this was to be done he would allow nobody to know, but he exhibited samples of sugars which certainly were superior to the ordinary run, and which he claimed to have been treated electrically. When a desire was expressed to investigate the process exhibitions were given at which the "machinery" was shown covered up with a cloth. As the result of these tests the company was formed, with a capital of a million dollars, and Freund was given 5,250 shares out of the 10,000. Of the remaining shares it is stated that some 300 or 400 were taken up in New York and Philadelphia, while over 3,000 went abroad, most of them being bought up in England, where the greatest interest appears to have been taken in the matter by sugar brokers and refiners. As soon as the company was well organised and in possession of funds, which came from the sale of stock a factory was fitted up over in Brooklyn as a "blind." It was supposed that large quantities of machinery had been put in there, although the exposure which has now been made by breaking into the place reveals little more there than a lot of tables, tin pots and pans, barrels of chemically-refined sugar, and a lot of raw sugar, closely resembling that which from time to time has been carried to the factory for treatment, and has been supposed to have been submitted successfully to the wonderful refining process. Recently, in spite of the death of the inventor, the price of the stock had risen very high, reaching as much as $300 or $400 a share; but a little nervousness was aroused among American stockholders a few days ago, when it was found that the inventor's widow and other members of the family had gone West for parts unknown. The fugitives—for such they seemed to be—were immediately hunted up, and on being discovered and requested to hand over the details of the valuable secret, Mrs. Freund cooly asked whether a process for treating refined sugar would not suit them. This was declined with thanks, and on the news being wired to New York, the mysterious Brooklyn "factory" was broken into, with the result above stated. Shares immediately tumbled to an insignificant value, the whole swindle was made public, and now there is a demand for vengeance on the part of the deluded stockholders here, which is no doubt echoed by the Englishmen who have invested, and who seem to have been worse bitten than anybody else. It is extraordinary that this thing should have gone on so long and that the parties to the swindle should have been able to maintain the deception, and the only inference is that some of those who were in the management, other than the inventor and his family, must have had a pretty good inkling of the true state of affairs. It is some satisfaction to know that electricity had nothing whatever to do with the matter, and that the name "electric refining" was simply assumed for the greater effect it might have on the public. It is a remarkable story of credulity, but no age has been without these examples of blind cupidity, and it may be taken for granted that this is not the last of the series. In fact, there is an analogous case at the present time in the Keely motor, whose supporters have been putting in their hundreds of thousands of dollars for some years past, and who are as far as ever from the knowledge of Keely's secret or any details of the new force of which Keely announces himself as the discoverer. It may be noted, by the way, that Keely, too, now claims to have electricity somewhere in the apparatus. That is an after-thought, and a shrewd one. Still, this sugar-refining *exposé* ought not to be without its lesson for the investors in Keely's stock, and probably we shall hear that it has stirred them up effectually.

I presume that most of your readers have seen notes in the daily papers of the present condition of affairs in Hayti. The inhabitants of that West Indian Island Republic are almost without exception black or brown, and ever since they escaped the yoke of France have done little but squabble among themselves, each autocratic president holding office as long as he had power to do so, and then in turn making room for some less scrupulous and more bloodthirsty successor. The Haytian people, as a rule, are kindly and good natured, but they cannot be said yet to have mastered the science of politics, and hence their history for many years has been a record of internal warfare. At the present time two factions are contending for supremacy, and they are varying the monotony of their otherwise commonplace revolutions by seizing some of our merchant ships. Owing to this fact, there has been great demand and anxiety on the part of the newspapers and people to obtain news from that part of the world, and there has been strong complaint because very little news by cable has been obtainable. The service for the British West Indies has, as you know, been largely carried on by the West Indian and Panama Telegraph Company, which, after a long career, has still to earn the goodwill of the colonists. Latterly a new French cable company has been making connections with the West Indies, but it alleges that it has been blocked by its old competitor and by the Spanish authorities, on the ground that the West Indian and Panama Telegraph Company possesses the monopoly of landing cables in Cuba. The latter company has the support and co-operation of the Local Cuba Company, and the International Ocean Telegraph Company, and the Western Union Company; hence the French company finds itself cut off from communication with the American mainland. This is unfortunate, as the French company touches at the northern part of Hayti, in which the troubles have been the most pronounced, and some of the papers are very severe in their criticisms on the situation, which prevents them from getting early intelligence at such a crisis. Still, I do not exactly see what is going to be done about it. It is hardly likely that the older companies will give up any of their rights or privileges, especially as cable service in the West Indies has not yet, as far as can be learned, been very profitable to the companies interested.

While speaking of cables, I may make a note of the submarine cable which is now being made in this city by the Bishop Gutta Percha Company, one of our oldest manufacturing concerns. It is intended to connect the islands of the Sandwich group in the Pacific Ocean, and is being made according to specifications furnished by Captain Samuel Trott,

Digitized by Google

the well-known cable-laying pioneer, now in command of the repairing steamer "Minia," and by Mr. F. B. Hamilton, his electrician. This cable, which is some forty miles in length, is, it may be noted, entirely unarmoured. The stranded copper conductor is first insulated with gutta percha, which is then covered up with soft hempen yarn, saturated with pitch, over which again is a protective jacketing of harder twisted hempen yarn. The cable is weighted and stiffened by being loaded between the layers and threads with a compound of mineral pitch and silica, a heavier coat of which is put on the outside by running the cable through dies prepared for the purpose. The silica is also said to serve the useful end of protecting the cable against the vicious attacks of teredo. It will, perhaps, be remembered by many of your cable readers that Captain Trott has long been an advocate of this species of unarmoured cable, some of which is probably already in use, and it will certainly have an opportunity of showing its efficiency in the deep waters of the Pacific where, if report be true, it is likely to find extended application in some of the plans that are now rapidly maturing for the telegraphic occupancy of that vast stretch of ocean. Our manufacturers have not, up to date, done much in the line of submarine cable manufacture, but this looks like a new departure in that respect, and it is worthy of note that the work should have been given to so old a concern, which, though perhaps not widely known in England, has long had a high reputation here. Bishop cables, I might add, are also in use in connection with the successful work carried out by our light-house board in illuminating the Gedney Channel approach to New York harbour by incandescent lamps.

The big Edison consolidation is now in a fair way of being carried through. The announcement was made this week of the incorporation in New Jersey of the Edison General Electric Company, with a capital stock of $12,000,000, in 120,000 shares of $100 each. This immense organisation is to take over the various Edison manufacturing plants, including the Edison Lamp Factory, the Edison Machine Works at Schenectady, the factory of Bergmann and Company in New York, and the Edison laboratory plant at Orange. The parent Edison Electric Light Company comes into the combination, with all its patents and stock interests in subordinate companies, so that the new corporation starts out with highly valuable assets, and should be in a position to make a fair return from the outset upon the whole of its capital. Specific details of the scheme are still wanting, but the above is the plan in its broad scope and outline. It is said that there will be closer technical affiliations with European concerns, and that on both sides of the Atlantic, especially in Germany, the Edison system will be vigorously pushed. These new arrangements should prove beneficial to Mr. Edison in a financial way, as he has always been a large holder of stock, and there seems no reason to believe that his personal importance, financial or otherwise, will be any less than it always has been.

So far we have been enjoying a remarkably open winter, and the consequence is that electric railway contractors have seized the opportunity to do a little of the work they have in hand. The Bentley-Knight people have been busily engaged preparing Fulton-street, in this city, for the operation of their conduit system. As heretofore employed, this system involved the use of a conduit between the rails of each track; but in the newer and later work, as is exemplified in Boston and here, the conduits are placed not between the rails, but between the tracks. This, of course, is advantageous in allowing for drainage by a single catch-pit and sewer connection, placing the conduits at the crown or highest point of the roadbed, and interfering in the least manner possible with traffic by horses during the period of construction.

The plow which is used in the Bentley-Knight system for contact with the conductor in the conduit is now placed at the side of the car, inside the space occupied by the car step, so that both it and the opening in the conduit slot are covered in such a way as to offer no danger to passengers or obstruction to traffic. Reports from Boston state that a section of conduit on the West End road there has been put into operation, and promises to work well. If the Bentley-Knight system succeeds on Fulton-street it will succeed anywhere.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *January* 22, 1889.

The central station erected by the Continental Edison Company at the Palais Royal was started last Saturday in the presence of the Minister of Public Works and some other important people. The current is distributed to about 2,000 lamps placed in the shops around the gardens of the Palais Royal, but will be shortly extended to the Theatre François, the Theatre du Palais Royal, the Conseil d'Etat and the Cour des Comptes.

The boiler room contains at present five Belleville boilers, and two more will be added later on. The water supply is assured by three large reservoirs, having a total capacity of 158 cubic metres (34,580 gallons). These reservoirs can be supplied from a well by means of a centrifugal pump, driven by an Edison machine, or from the town mains. The smoke is taken along a tube 27 metres in length to the chimney in the Rue de Valois, where the exhaust steam is also discharged. The engine room, which, as your readers will recollect, is under ground in the middle of the main court of the Palais Royal, is 21 metres by 28 metres, and contains the two condensers, the dynamos, engines, and switch-board. At present there are four 150 horse-power Weyher and Richemond engines *in situ*, running at 130 revolutions, and each driving direct on to an 88,000-watt Edison dynamo (110 volts and 800 amperes). There is sufficient room for double this plant. The distributing switch-board is of the same pattern as that in use at the Grand Opera.

The Thomson-Houston system is increasing rapidly in Paris, and in the first fortnight of this month over 200 new arc lamps have been installed at the Theatre des Variétés, the Eden Theatre, the Skating Palace, &c. I have been told that a part of the Boulevards will be lighted during the Exhibition with 200 lamps of this system, and it is certain that this lighting, put up for temporary use, will remain there definitely.

All the firms to which concessions have been granted are rapidly preparing to set at work as soon as possible, and hope to start stations at the opening of the 1889 Exhibition. The time is, however, short, but great efforts are being made by every one, and some will be ready by this time. In the meantime private installations are regularly erected, and scarcely a single day passes without one shop or another replacing gas by electricity. The new light increases in favour also in the provinces. Last Friday the concession for Le Havre was granted to a Paris firm; Bordeaux lights its quais, and Nimes, Marseilles, &c., are engaged in serious negotiations. In one word, electricity gains ground rapidly everywhere in France.

The suit brought by the Société Générale des Téléphones against other French telephone makers for infringement of the patent Edison coil has been decided against the aforesaid company, in spite of a favourable report made by the experts, Potier, Perissé and Co. But the Société Générale des Téléphones will not accept this decision as a final one, and the case will be brought before the Court of Appeal, where this company hopes to be more successful.

NOTES FROM BRUSSELS.

(FROM OUR CORRESPONDENT.)

BRUSSELS, *January* 21, 1889.

The Special Committee appointed by the Conseil Communal of Brussels for the purpose of studying the question of electric lighting met on the 12th inst., and finally decided on its report. This committee, which consists of MM. Bède, Pilloy, Yseux, Depaire, and Wybauw, and is presided over by M. Janssen, advises the authorities to undertake themselves the supply of current for lighting and power purposes. This result was foreshadowed by me in a recent letter, and will, I am afraid, be little to the taste of the electrical syndicate. I trust that we shall not see the great mistake of long concessions repeated; the supply of gas, water and electricity is an attribute of the local authorities, who ought to distribute it in the interests of the inhabitants and not for the benefit of speculators. The question as to whether Belgian firms alone shall be allowed to compete is a secondary matter, so long as no one but the authorities is allowed to fix the price and regulate the conditions of distribution. The Conseil Communal have been well advised—and now to work.

The new installation on the Place Rogier has just been inaugurated. The effect is prettier, but there is not much more light than before.

BRUSSELS, *January* 23, 1889.

The Conseil Communal has occupied itself during its recent sittings with the electric lighting question. The present intention of the authorities is to invite tenders, so that a definite decision can be arrived at within the next month or so. The exact basis

Digitized by Google

upon which the tenders will be invited will be settled by the Special Committee, but I think there is little doubt that any system whatsoever will be allowed to compete. A single well-placed station might suffice for all the central portion of Brussels, and if a low-tension system is decided on it will probably be constructed in the north pavilion of the Halles. If, on the other hand, high-tension distribution is employed, the station might well be situated near the gasworks, three kilometres from the Boulevards. In the former case the land would cost 500fr. per square metre, and in the latter only 5fr. the square metre. Amongst the first places to be publicly lighted will be the inner Boulevards, with 120 12-ampere arcs, the park with 80 arcs, and the Theatre Flamand. The security which the contractors will have to deposit will amount to a tenth of the contract price. The tenderers will have to give full details with regard to the power and type of the engines, the method of driving the dynamos, their commercial efficiency, speed, &c. Preference will be given to Belgian machinery, all things being equal.

Now that the question of electric lighting has taken such strides it is interesting to recall some of the earlier efforts which were made in this city. In 1882 the Théâtre de la Monnaie was lit by accumulators, which have since been replaced by the present method, which has proved much more satisfactory. Then, in 1883, the Théâtre du Parc was temporarily lighted by the Edison Company. Since then we have had the Grande Place and the Hôtel de Ville lighted by electricity; the latter installation will shortly be run off accumulators at the Maison du Roi, the cells being charged from the Laeken central station. Private installations also have largely increased, and it is now clearly time for the town authorities to take the matter up.

CORRESPONDENCE.

TELEGRAPHY WITHOUT WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the *Electrician* for November 9th I called attention to a somewhat remarkable disturbance on a short telephone line running between 75, Queen Victoria-street and 59, Knightrider-street, E.C. In your issue for November 16th Mr. F. Higgins suggested that this disturbance might be due to induction from one of his company's exchange telegraph wires; but on making one or two experiments, and hearing the disturbance himself, Mr. Higgins subsequently was satisfied that this was not the correct explanation of the phenomenon.

Through the kindness of Mr. W. H. Preece the whole matter has since been thoroughly investigated by Mr. W. Brown, of the Central Telegraph Office, and I am able to give a *résumé* of the experiments, which may interest some of your readers.

Between 75, Victoria-street, and 59, Knightrider-street, there are two No. 16 B.W.G. hard-drawn copper wires running parallel. The wires are each about 110 yards long, consisting of two spans suspended about 80 feet above the street level. They could be looped or used singly as well, and in the latter case the earth connections were made at each end to either gas or water pipes. There was no disturbance when the wires were looped.

The disturbance was traced as being caused by the working currents in the Postal Telegraph news wire running from the Central Telegraph Office, St. Martin's-le-Grand to Brighton and Portsmouth. The route followed by this wire—which in the City is entirely underground in an iron pipe—is *viâ* St. Paul's Churchyard, across Cannon-street, down Old Change, across Queen Victoria-street, along Upper Thames-street, over Southwark Bridge, and thence to New Cross. No portion of this wire—at any rate on the north side of the Thames—is exactly parallel with the one on which the disturbance is heard, but where the former passes along Upper Thames-street the two are nearly parallel, though from 80 to 100 yards apart.

The Post Office wire is worked with 30 bichromate cells and Wheatstone automatic instruments, the normal speed of working being 350 words per minute, this representing a frequency of 16,800 currents per minute. This circuit was identified as being the one that caused the disturbance by arranging the Wheatstone transmitter to send plain reversed currents and breaking the line connection. When Morse signals were transmitted in this manner they could be read perfectly distinctly on the telephone receiver at 75, Queen Victoria-street, as also at 59, Knightrider-street, the signals so received being similar to the vibrating signals produced with the "buzzer" instrument used for military purposes. Both Bell and Ader telephones were used as receivers, the latter giving the loudest and most distinct results.

After the disturbing circuit had been thus identified, several experiments were tried to determine in what way the interference took place. The earth connection of the Wheatstone transmitter at the Central Telegraph Office was removed, and wires earthed at Clapham Junction and at London Bridge in turn substituted, without having any appreciable effect on the disturbance. On the section of the disturbing circuit between St. Paul's Churchyard and Thames-street being changed, and a fresh wire in the same pipe substituted, the interference was still felt, but was to some extent reduced, probably by one-fourth.

Another wire which runs underground *viâ* Cannon-street was next substituted for the one *viâ* Thames-street. The disturbance was still heard, but was reduced in volume by about one-half. A wire *viâ* the north side of Cheapside was next experimented upon, it being substituted for those through Thames-street and Cannon-street previously tried. The interference was now reduced to about one third of the normal, but it was still quite easy to read the signals. After this a spare wire was earthed at the junction of Thames-street and Queen Victoria-street. This wire runs from the Telegraph Office in the same pipe as the original disturbing wire, and was substituted for the earth at the central telegraph office on the Wheatstone instrument. When this loop was used the interference was considerably increased in loudness, from which it appeared that the loop wire was not earthed far enough away. The spare wire was therefore extended in the same pipe as the disturbing wire as far as the Old Kent-road, and there earthed. Upon again substituting this spare wire for the earth of the Wheatstone instrument the interference was practically neutralised, being reduced so as to be only just audible above the general disturbances which affect the wires. No doubt had the two wires been twisted, absolute silence, so far as the disturbance due to the Wheatstone instrument was concerned, would have been obtained.

These experiments seem to prove conclusively that the disturbance is due to induction pure and simple. The fact that when the Wheatstone instrument was earthed at Clapham the disturbance was in no wise diminished shows that it can scarcely be a matter of earth leakage. It would, however, be interesting to know whether the effect is simply a case of direct induction through space between wire and wire, or whether the earth in some more or less secondary capacity has any thing at all to do with it.

It cannot be claimed that the above results are novel, as they only bear out those previously obtained by Mr. Preece in the Severn Valley and elsewhere, and described by him in 1887 at the British Association meeting at Manchester; but still it will, I believe, surprise not a few that the electric currents in a wire laid underground in an iron pipe passing along Cheapside should so influence surrounding space that, no matter the buildings in the way, a telephone connected to another wire only 110 yards in length, suspended 80 feet above the level of the ground, and nearly 300 yards distant, should faithfully and loudly repeat every electrical impulse.

That a current only a few milliamperes should affect all space within a radius of at least 300 yards to an extent capable of appreciation by human senses is certainly a wonderful instance of the natural transmission of power; but perhaps when we come to remember the enormous distances through which luminous radiations—probably electro-magnetic in their nature—are propagated without sensible loss through space, we shall recognise that it is merely because the former phenomenon is more unfamiliar than the latter that we think it more remarkable.

Apologising for trespassing at such length on your valuable space.—Yours, &c.,

66, Victoria-street, S.W., January 21, 1889. A. A. CAMPBELL SWINTON.

MR. EDMUNDS' METHOD OF MAINTAINING CONSTANT CURRENT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to the letter of Mr. Bate on the above subject, I would say that I did not intentionally ignore the remarks of Mr. Preece or himself in my reply to the discussion; for the allusion to this mode of obtaining constant current was rather an incident than otherwise in my Paper on "Electrical Distribution," and I did not wish at that time to give it the prominence which it deserves, only desiring to indicate that I was working in this line, rather than to enter into full details in connection with it.

I, however, take this opportunity of saying that I first observed that constant-current machines would automatically speed themselves if they had a constant pressure of steam, during the early work I did in lighting the Liverpool-street Station by the Farmer-Wallace system in the winter of 1878. We there employed a Robey steam engine, and I was not a little surprised to find on one occasion that when the governor belt broke the engine did not run away, but maintained a given speed with the then given load of, I believe, six arc lights. One of the arc lights happened, through some derangement, to short-circuit itself, which was immediately attended by a lowering of the speed of the engine, without any alteration of the valve by the engineer in charge. Though I made this observation so long ago, it did not occur to me until more recently to apply it practically, from the fact that we did not get steady motion with comparatively slow-speed engines, such as were then used, and, further, in most of the then installations a uniform speed in the engines was a necessity, and elaborate governors of all kinds were brought forward for this purpose. Many of the engines were expected to drive other work beside the dynamo, and some to drive two or more dynamos, so that it was better to have a constant speed than a variable one. In order to do this, I suggested to Mr. Richardson, of the Robey Company, that a governor might be made that should automatically control the steam admitted to the engine, by variations in the current, thereby effecting a mode of regulation in the same way as the Richardson and Willans governors. But with ordinary constant-speed engines regulators have been devised by constant-current dynamo constructors, such as Thomson-Houston, Brush, and Hochhausen, in which they avail themselves of a constant-speed engine and dynamo, keeping the current constant, but varying the E.M.F. in accordance with the variations of the work by their several methods of varying the adjustment of the brushes and the regulation of the exciting field, such regulations being attended by the variation of the supply of steam by the automatic governor of the engine; but I believe that I can show that these elaborate regulations are not necessary.

When I had an opportunity, such as presented itself at the Cadogan station, of employing a fairly large dynamo of, say, 28,000 watts, requiring a constant current with a variable potential, and having also such an excellent engine as the Armington-Sims, which can be run at high rates of speed, maintaining meanwhile a full passage through the ports, I thought it was a good opportunity for putting into practice my observations of ten years ago, and to employ several individual engines, each running separate dynamos, rather than put all the work on to one engine with one large dynamo or several small ones. The apparent paradox as to why a machine doing less work should run at a less speed generally presents itself as a difficulty to anyone looking at this question for the first time, but I think it is not difficult to explain this satisfactorily if we look at the question in another light. I would ask Mr. Bate to imagine the following conditions, very similar to those we have in practice at the Cadogan station, and cite the example he gives in his own letter: "The engine, the starting valve of which has been opened, so that it drives the dynamo just fast enough to generate 70 amperes at, say, 10 volts [or, better expressed, say "fast enough to generate 10 volts by 70 amperes"] = 700 watts, say 1 brake horse-power—will, without attention to anything except the maintenance of a constant steam pressure of 70 pounds on the boiler, and without alteration to the starting valve, increase its speed until it gives 70 amperes at 2,000 volts = 140,000 watts, or, say, 200 brake horse-power." The only difficulty in his proposition is a mechanical one. I should not care to run either the dynamo or the engine at the speed required to give off this energy, but there is no electrical reason why it should not be done. Let us, however, follow his illustration up to 500 volts, which we see might mean the dynamo running at 1,000 revolutions (that is, two revolutions per volt), and I will now ask him to follow me in the subjoined remarks.

70 amperes by 10 volts may be taken as 20 revolutions of the dynamo. We will say that the engine is speeded proportionately—that is to say, at a third of the dynamo speed. It would then be going at about six revolutions. This would be in the condition that Mr. Kapp very properly objected to, but this objection is overcome by the fact that the machines are never worked with a less external resistance than one ohm or say a line of two miles of $\frac{3}{8}$-inch conductor. One ohm, resistance to 70 amperes on such a line would represent 70 volts, or 140 revolutions of the dynamo, or 46 of the engine. This is practically the minimum speed. Now, why does the engine with full valve not run away? That is the question, and the answer is that 70 pounds of steam cannot generate more than 70 amperes of current under the proportions of the area of the piston and speed considered. Supposing, however, that more work is put on so that the external resistance is doubled. It will be observed that, at the moment when this extra resistance is put in, the dynamo is running at 140 revolutions, giving 70 volts by 70 amperes, through 1 ohm; but it suddenly meets with 2 ohms resistance, and the E.M.F. accordingly rises to 140 volts, and the current falls to 35 amperes. This practically liberates the engine, which was held back by 70 amperes; and it commences to speed up—that is, provided the port ways are open and there is a good head of steam—until the dynamo again comes up to the resistance, to 70 amperes, which again acts like a brake on the engine, and the speed of the dynamo becomes 280 and the engine about 93. We increase the work further, either by the addition of more line resistance or more battery resistance, and every increase of resistance placed in the line causes the dynamo to lower its current value, which is immediately attended by the speeding up of the engine, until it reaches the mechanical limits of speed at which we deem it desirable for the dynamo and engine to run—say, a maximum speed for the dynamo of 1,000 revolutions, and the engine about 333. Now, if Mr. Bate takes these figures at this point he will find that we have 1,000 revolutions, 500 volts, 70 amperes, and 50 horse-power, which he will see is proportionate in each case.

Let us now reverse the operation, and cut down the external resistance. We will find that when the resistance is cut down one half the result will immediately be that, with this speed and E.M.F., the current will have the effect of a brake on the engine, and reduce the speed; not because we turned off the steam, but because we gave it more work than that pressure could overcome. But as the engine slows down so the voltage diminishes, and it is found in practice that when the engine slows down and the E.M.F. falls until the current is again 70 amperes, it will have just slowed down to half of what it was previously, viz., 500 revolutions of the dynamo, with 70 amperes of current, with an engine-speed of 166. Let us again halve this, and we find the same rule applies, until at length we can literally short-circuit the dynamo through one-seventh of an ohm resistance, which would require only 10 volts, coming back to where we started; and I maintain that, with these conditions, it is not necessary to resort to the complex arrangements alluded to by Mr. Bate.

It is also interesting to note that we have an indication of the measure of the work at any time under these conditions by simply reading the number of revolutions from a tachometer on our dynamo, first noting that the steam pressure is 70 on the boiler.—Yours, &c.,

HENRY EDMUNDS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your correspondent, Mr. Bate, takes exception in your last issue to Mr. Edmunds' statement that an engine driving a separately-excited dynamo will, without a governor, adapt itself to the work it has to do in maintaining a constant current,

Digitized by Google

whatever may be the resistance in the external circuit. It appears to me that, *within limits*, Mr. Edmunds' statement is quite correct. The conditions I think, however, are hardly sufficiently strict. I should be inclined to say that one condition was that the passage from the boiler to the engine cylinder should be very free and unobstructed, so that the pressure on the piston may be practically always the same at whatever speed the piston is running. Were it not that this condition is difficult to secure in practice for large variations in speed, and that it requires that the engine itself should be carefully proportioned to the dynamo and current, and also that the friction of bearings, &c., produce different effects at different speeds, it would be a simple matter. It is clear that if the pressure in the rear of the piston is in excess of the resistance to its movement offered by the torque of the dynamo and other resistances transmitted through the piston rod, the piston will accelerate its speed until the E.M.F. of the dynamo and, consequently, its current and torque, increase sufficiently to balance the pressure on the piston. If now the resistance in the external circuit be increased, the current will diminish, and with it the torque; the engine will thereon accelerate its speed until the current has pretty well reached the normal amount. In practice, however, it would, I think, be found that, principally owing to the loss of steam pressure by friction in the passages, which would obviously increase as the quantity of steam passed per minute increased, the current would fall somewhat as higher E.M.F.s and speeds became necessary, and that unless an electrical governor were used it would be necessary to have a certain proportion of shunt wire on the field-magnets to compensate for the engine running somewhat slower than theoretically it ought to do.

With respect to the question why is it necessary to use a separately excited dynamo, I should be inclined to agree with your correspondent that it is not necessary, and that a series-wound machine should give the same result, the only point occurring to me with respect to this being that some "hunting" effects might come in, owing to the magnetisation of the magnets varying as resistances were inserted and taken out in the external circuit. With respect to his last paragraph, I think your correspondent has hardly appreciated the fact that one of the main objects of most builders of engines is to drive them at the greatest speed to which they can be worked without flying to pieces by centrifugal force or knocking themselves to pieces under the influence of reciprocative action, and that a large proportion of the improvements in modern machinery have for their object the safe driving of engines at higher and higher piston speeds.—Yours, &c., R. H. C. Neville.

Wellingore Hall, Grantham, January, 21, 1889.

REFUSE DESTRUCTORS AND THE ELECTRIC LIGHT.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your paper of January 11th you refer in somewhat flattering terms to a scheme for using the town refuse for driving an electric light installation for Derby. The quality of town refuse varies greatly in different towns, depending somewhat on the price and quality of the coal used in the neighbourhood. In the case of the 150 tons referred to, all the dust is supposed to be taken out, but that being done you only assume it to be of one-third the value of steam coal for steam-raising purposes. This I consider very low indeed for such fuel as there is here; but even at this low rate you get a result of 220 horse-power continuously, or 440 horse-power 12 hours per day, whereas in a recent Paper of mine I set down 450 horse-power 15 hours per day. I enclose you a copy of my Paper. It is now over four years since I first mentioned this scheme to the late T. Coulthurst, Esq., borough engineer for Derby, and the matter obtained very little notice until I again introduced the question about six months ago, and I am pleased to say to all appearances with better results. You, however, will scarcely believe that nine months ago I sent a copy of this scheme to a local authority in the South of England, who wished to use up their refuse for electric lighting purposes, but they did not as much as acknowledge my communication. I must thank you for the notice you have taken of my scheme, and beg leave to say my only object is to prevent the waste at present going on in burning good fuel simply to get it out of the way; there is no monetary reward in this scheme, there being no patents or royalties connected with it, so I cannot be termed an interested party in a monetary sense.—Yours, &c.

F. W. Brookman, Refuse Destructor Foreman.

THE PHYSIOLOGICAL EFFECTS OF ALTERNATING CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Your American letters have latterly said a good deal about the relative danger of alternating and direct currents employed in electric lighting. Nobody cares to let their own body be the arbiter in this dispute, and I do not pretend to say that the trial I have made myself is conclusive on the point; but for what it is worth I will describe it, especially as the instrument referred to is plentiful in this country, and little used in America. The experiment is as follows:—Attach two wires (with suitable holders for the hands) to a Wheatstone automatic transmitter. If the hands are in a normal condition of moisture the experimenter will be able to retain his grasp of the holders at a very high speed without any alarming symptoms. The first shock at starting is probably the hardest to bear. A strong man, not troubled with nerves, will bear the rapidly alternating currents at full speed. What relation this bears to the speed of an alternating current dynamo I do not pretend to say; but my general impression after repeated trials with the Wheatstone transmitter is that its current becomes alarming only when the speed reaches a point when the centre of the body—not the arms alone—experiences the sensation, and when the nervous conviction arises that the experimenter will not be able to leave go the holders if he tries, which is generally the case. But now comes the curious fact: If the instrument is gradually *slowed*, the shocks become painful, until at length they are quite unbearable. I do not say they frighten the patient as much as the very rapid currents; I am only speaking of physical effects; and I say emphatically that while the high-speed currents can be borne when the experimenter is not in a funk, *the slow currents cannot*. Or to put it differently, the slow currents give a great deal more physical pain than the rapid currents. Of course it follows that a single powerful shock has far greater effect on the sensation than the same current rapidly alternated. It does not perhaps necessarily follow that a death-dealing current would be rendered harmless by being made alternating; but if the relative *pain* caused by the two kinds of shocks be any criterion of their probable effect on life, it would seem to follow that an alternating current is the least fatal. Telegraphist.

London, January 22, 1889.

ALKALINE ACCUMULATORS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In Mr. Elwell's remarks on the above subject in your issue of the 18th inst., I notice that he mentions that the zinc is deposited on iron gauze. May I be allowed to ask how long such an accumulator will hold its charge, since zinc is dissolved in alkaline solutions when in contact with iron? This fact appears to be of great importance, especially when the battery is used, as the writer suggests, for miners' lamps, or in any case where the discharge is spread over a long period.—Yours, &c.,

London, January 23, 1889. A. E. Greville.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In his article on "Alkaline Accumulators," in your last issue, Mr. P. B. Elwell describes a portable combination in which a negative of compressed silver powder, with a zinc positive in an alkaline electrolyte, is used. Now such a combination has been employed by me for some considerable time, dating so far back as 1881, and should confirmatory testimony be needed it could readily be produced, as batteries made on this principle, both primary and secondary, were made and sold by the firm I was at that time connected with. Of course I do not say that my method of working is identical with that described by Mr. Elwell in all

Digitized by Google

details; as is to be expected the methods differ somewhat in detail of construction (for instance, I use an amalgamated zinc plate simply, his friends iron gauze upon which zinc is deposited; I support the compressed silver powder on a thin plate of silver, usually foil, but they have succeeded in making the compressed powder self-supporting), but I think I have said sufficient to show that I am entitled to put on record the fact that I have been working on very similar lines to Messrs. Dezmazures and Commelin for a considerable time. I am still the more desirous that such fact should be recorded, as, should I (or my friends) be disposed to make further use of my method of working, the risk of being accused of copying the alkaline accumulator of Messrs. Dezmazures and Commelin will thereby be prevented.—Yours, &c.,

January 23, 1889. H. J. COATES.

BATH ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should not have troubled to reply to the letter of the secretary of the above company had he confined himself to facts; but he tries to mislead your readers by what I can only describe as a perversion of the truth. He asserts that the Bath Corporation have "somewhat reluctantly" concluded a contract with me, &c. The exact contrary is the case. At my suggestion the Corporation decided to entertain lighting all the principal thoroughfares with arc lamps, and grant facilities for the supply of private lighting. This question has been under their consideration for more than twelve months. Advertisements for tenders appeared for two successive weeks in each of the electrical journals; each contractor was required to tender for overhead and underground mains. Ten tenders were received, of which the one sent in by myself (on behalf of a local supply company) being the lowest, for both overhead and underground mains, was accepted. All those who had taken the trouble to make themselves acquainted with the peculiar difficulties in the way of running underground in this city recommended overhead wires, and the majority of the Corporation being of the same opinion, that method was adopted. At the meeting when the final vote was taken of a Council numbering fifty-four members, only one gentleman voted against the contract being signed.

Considering that gas for the public lamps is charged only 1s. 11d. per thousand in Bath, the well wishers of electric lighting throughout the country were surprised at the almost unanimous vote of the Council. In common with others, the House-to-House Company had the opportunity of tendering, but it does not appear to have answered their purpose to enter the field of fair and open competition.

The following report of what took place when the application of the House-to-House Company was read shows the feeling of the members of the Bath Council:—

Mr. Cox said that was an application for another company to go in and do the work which another company was engaged to do, and before they knew how it was to be done. They were in a transition state at present, and no interference should be allowed.—The Chairman: How can we, after arranging with one company, entertain proposals from another?—Mr. Sturges: We would not be allowed.—The Chairman: Well, I do not think so.—Mr. Mitchell then moved, and Mr. Sturges seconded, that the matter be referred to the Electric Light Committee. This was unanimously agreed to.

The opponents of electric lighting in Bath are delighted at the "dog in the manger" policy of the House-to-House Company, but the friends of electricity naturally regret it. The insinuation of the secretary of the House-to-House Company to the effect that they possess the most perfect installation yet constructed, and are the only people capable of undertaking central station work, may be correct, or it may be their opinion only. In any case I prefer to employ firms of standing and repute, who have already given me unqualified satisfaction, but whose names I purposely withhold, as I do not wish to make your correspondence columns a means of advertising any particular firm or company. The secretary of the House-to-House, in true imitation of the Maxim-Weston Company in its worst days, refers to my calling in terms neither true nor complimentary. I am usually described as a boot and shoe manufacturer and leather merchant, but this gentleman very politely designates me a "boot and shoe maker."

During the past four years my association with the electric lighting industry has been of a most agreeable character, and all professional electrical engineers with whom I have come in contact have been honourable business men, and gentlemen, but the promoters of the House-to-House Company appear to be exceptions to this rule.—Yours, &c.,

H. G. MASSINGHAM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Shylock may have been legally entitled to his pound of flesh, and rival companies may be legally entitled to engage in cut-throat and disastrous competition; but the question as to what is fair and just also deserves consideration.

I think the electrical profession will in general agree with me that the action of the so-called "House-to-House Electric Light Supply Company at Bath is calculated to have a prejudicial effect on, and is antagonistic to, the progress of provincial electric lighting.

It would be interesting to learn how many thousand lamps are at present being supplied from the central station, "which is by general admission the most perfect of its kind," and the mileage of underground mains connected therewith.

I am personally unacquainted with Mr. Massingham, and in this case simply, Yours, &c.,

A DISINTERESTED OBSERVER.

Liverpool, 21st January, 1889.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The thanks of every true friend of electric lighting progress are due to you for the well-merited rebuke contained in your editorial note appended to a letter appearing over the signature of H. St. John Winkworth in your last issue. That the tactics of the now happily defunct Maxim-Weston Company, as directed by Mr. Watt, should be again revived would be an eventuality against which the best efforts of every member of the electrical engineering community, backed up by the whole power of the scientific press, could not be better than employed.

It is not the energetic prosecution of legitimate business which is to be complained of, and no firm with a reputation to keep up objects to open competition, but the underhand system which certain so-called and self-styled pioneers of electric lighting adopt, of waiting until a contract is either absolutely signed or on the point of signature, the burden and heat of the day having been borne by others, and then, and not till then, stepping forward to reap the harvest, if possible, but, any way, to turn the other man out, even if total abandonment of the project should follow.

Granting, for the sake of argument, that the engineers of the House-to-House Company have laid out a station with underground mains, what right has Mr. Winkworth to trumpet forth the achievement as the *only* central station so arranged? Is he such a late acquisition (?)—save the mark—to electric lighting ranks that he has never heard of the Edison station in New York, besides others of later date at Chicago and elsewhere, both on that and other systems; or, to come nearer home, has he never heard of the Kensington Court, Metropolitan Electric Supply, Chelsea Electricity Supply, and others, all using underground mains?

Although Mr. Winkworth may not be aware of it, electric lighting with underground mains has been going on for some years now—going on successfully, too—and some of us, having been "in it" from the first, can afford to smile at the cry of "only show in the fair" which the fresh men make.

Not wishing to get a free advertisement for myself out of you, Mr. Editor, I beg to sign myself—Yours, &c.,

MARSDEN.

"ETHER."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you kindly permit me to offer a few remarks upon the leading article in your impression of the 18th inst.?

Somewhat startled at the statement therein made that "the pressure of ether per square inch (under, or rather within, which

Digitized by Google

we live and move and have our being) must be about seventeen billions of pounds," I made a rough calculation, based upon the well-known law of the relation between wave-propagation, density, and elasticity. Taking the velocity of sound in air as 1,100 feet per second, and the velocity of the waves of radiant energy in ether as 192,000 miles per second, the ratio for the two media is approximately one million. Now, according to this law, for media of equal density the elasticities are directly proportional to the squares of the velocities of wave-propagation. Whence, for ether *with the same density as air on the earth's surface*, the electric force would be fifteen billions of pounds. Applying corrections for modifying influences on sound velocity in air, it is probable that the result given in your article, viz., seventeen billion pounds, would be obtained. But, fortunately for us, we do not live and move and have our being in ether so dense!

The value given in the earlier part of your article for the inferior limit to ether density in planetary space enables one to calculate the minimum elastic pressure exerted by the ether in that region.

This value is of course vastly below 17×10^{12}lb. per square inch. But even supposing the ether at its actual density to exert such an enormous pressure, one fails to see in what way this would modify one's belief in its existence. Having in view the "open structure" of matter, even of the ultimate atoms, two things are evident.

Firstly, that an excessively small fraction of the structure of any portion of matter is subjected to ether pressure. Secondly, that this pressure, being interatomic, as well as intermolecular (that is to say, exerted within and all around in equal amounts) no change in the chemical, physical, or dynamical condition of the body could be produced by it.—Yours, &c.,

The School of Electrical Engineering, E. T. CARTER.
Hanover-square, W., Jan. 23, 1889.

"THE TELEPHONE," BY PREECE AND MAIER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Would you kindly grant me space to correct an error which appears in this book. In the part treating of automatic cash boxes for public call offices the one described and illustrated at page 371 is stated to have been introduced into Manchester, whereas having been invented by Mr. Sinclair, engineer to the National Telephone Company (Limited), Glasgow, it was introduced, and is now much used, in that city and West of Scotland.—Yours, &c, J. M. Jun.

COMPANIES' MEETINGS & REPORTS.

Eastern Telegraph Company (Limited).

The thirty-third half-yearly ordinary general meeting of the Eastern Telegraph Company (Limited) was held yesterday (Thursday), the 24th inst., at Winchester House, 50, Old Broad-street, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. Draper) read the notice calling the meeting, and the minutes of the last meeting were confirmed. The report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, I will, as usual, give you some fuller details respecting the Company's working than are contained in the report. Our revenue for the six months ended September, 1888, amounted to £310,104, as against £291,265 in the corresponding half year of 1887, showing an increase of £18,839. The chief item of increase is from our holding of shares in the Eastern and South African Telegraph Company, the dividend on which is at the rate of 12 per cent. per annum, as against 8 per cent. per annum in the corresponding period of 1887, showing an increase of £7,800; the return for the half year from our investment in the Black Sea Telegraph Company is increased by £1,393; our Direct Spanish Shares have yielded an additional £307, interest gives us an extra £600, transfer fees £13, and our general traffic, chiefly South African and South American, £10,531. That makes a total of £20,644; but we have ceased to bring into our revenue accounts the dividend on Direct Spanish Company's Debentures, which are now considered as an investment for our reserve fund, so we must deduct £1,805, leaving the total increase at £18,839. The total working expenses for the half year amounted to £83,332, against £79,936, or an increase of £3,396. The details of increase and decrease are as follows:—General expenses in London, £7,845, against £8,012, or a decrease of £167. Working expenses at stations, £59,962, against £56,386, being an increase of £3,576. This is principally caused by the number of foreign staff having been increased to work the triplicate cable from Porthcurnow to Malta and extension to Zante, also the duplexing of same. We have also opened a new station at Cadiz, having put that place in telegraphic connection with Villa Real and Gibraltar. The laying of the new cable from Porthcurnow to Malta and Zante, besides giving us greater security and rapidity of working, has diverted to our system a large part of the Greek and Turkish traffic which formerly went *viâ* the Continent. The foregoing explanations also account in a great measure for the increase in travelling expenses, rent, stationery, and maintenance of instruments. A greater number of messages have been carried this half year than in the corresponding period, and the work to be performed by our staff increases year by year. £1,000 of the total increase in the working expenses is explained by our having carried £5,000 to our reserve fund for maintenance of ships, against £4,000 last half year. The repairs to cables amounted to £43,075, against £34,102, or an increase of £8,973. This is always an uncertain item in our accounts. Our ships have been busily employed in maintaining our system in a state of efficiency. The increase under this head is in the value of the new cable laid in, the total length being 130 miles against 38 miles in the corresponding half year of 1887. You will find on reference to the reserve fund that we have applied over £13,000 in reduction of capital expenditure, or, in other words, although we have spent over £13,000 in extending and improving our system, the capital expenditure remains at practically the same figure as last time. The Six per Cent. Debentures of the Direct Spanish Telegraph Company have been transferred to our reserve fund investments, which stand at £315,494, and our total reserves, after deductions, at £355,676. We pay the usual interim dividend at the rate of 5 per cent. per annum, and after providing for interest on Debentures, Debenture Stock and Preference Shares, we are able to carry £36,616 forward to our next account, against £29,397, or, £7,219 more than in the corresponding period of 1887. The Chairman afterwards reminded them of the full history which he gave of the Company at the last meeting, and stated that all the new Ordinary Shares had been fully taken up. The work of the South African Company's extensions was in hand, and he believed that at their next meeting, six months hence, he would be able to state that they had completed their West Coast of Africa cable—a work which would not be completed an hour too soon. The enormous traffic now going on to the Cape and the Transvaal, owing to the gold speculations, brought a great deal of grist to the Company's mill. With the completion of the cable mentioned, he believed that the Company would be able to meet all the telegraphic requirements of the public. Their system was working thoroughly well, but to maintain it in a complete state of efficiency—which they considered of vital importance to the welfare of the Company—their ships were kept fully employed; and he might add that, being in the neighbourhood of Suakin, they had given every possible assistance to the English Government while the Egyptian and British troops were in action there. This assistance had been greatly appreciated (cheers). Had they not duplicated their system and applied the duplex, they could not possibly have carried out the work they had done. The world could not live without the telegraph system, and they must see to it that they maintained their system in a condition of thorough efficiency. He concluded by moving the adoption of the report and accounts.

The MARQUIS OF TWEEDDALE seconded the resolution, and it was carried unanimously, after the Chairman had replied to a few questions and observations.

Resolutions were afterwards passed, re-electing the retiring Directors—Lord Sackville A. Cecil and Sir A. J. Leppoc Cappel—and the auditors, Mr. Henry A. Dever and Messrs. Welton, Jones and Co.

A vote of thanks to the Chairman and Directors closed the meeting.

[We shall publish a full report of this meeting in our next issue].

German Union Te'egraph and Trust Company (Limited).

An extraordinary general meeting of the members of this Company was held at Winchester House, Old Broad-street, on Tuesday, January 22nd, 1889, "for the purpose of considering and, if thought fit, passing special resolutions requiring the Company to be wound up voluntarily, and appointing a liquidator or liquidators for the purpose of winding up the affairs of the Company and distributing the property and fixing the remuneration of the liquidators." Sir James Anderson presided.

The SECRETARY (Mr. Wm. Payton) having read the notice calling the meeting,

The CHAIRMAN said that last March he told the shareholders everything it was then possible to tell them about the prospects of the winding up, and now they had come to the time for doing it. He was now able to tell them that the liquidators of the Berlin Company had declared a first payment of their Ordinary and Preference shares of 300 marks, or about £15 per share, which was their original par value. This sum would enable the liquidators of this Company to return to the shareholders about £7.7s.6d. per £10 share. A special extraordinary meeting would have to be held to confirm the resolutions now before them, when the liquidators would

Digitized by Google

immediately distribute *pro rata* the amount received on account of their return of capital. It was expected that they would be in a position to make the first payment in the first week of February, and the final payment by the liquidators of the Berlin Company would be made at the end of April. They hoped to complete the winding up of the English Company and pay the balance early in May. So far as they knew at present, they trusted to be able to make a total return to the shareholders of very nearly par. There had, however, been an accident to the cable, which had since been repaired; and until the cost of this had been ascertained he could not say finally what the result would be. In conclusion, he moved a resolution for the voluntary winding up of the Company.

Mr. H. G. ERICHSEN seconded the motion, which was unanimously adopted.

A resolution was next proposed by Mr. ERICHSEN appointing Sir James Anderson and Mr. William Payton liquidators for the purpose of winding up the Company and distributing the property, and fixing their remuneration at £200, in addition to the expenses incurred.

The motion having been seconded,

The CHAIRMAN, in answer to questions, said he thought the shareholders would be repaid nearly par, but he could not state definitely within a shilling or two what the return would be. The winding up was a matter of force. They had not worked the cable since January, and it was now entirely in the hands of the German Government.

Mr. WILSON said he thought that as that was the case the German Government ought themselves to have paid for the repairs which had been effected since January.

The CHAIRMAN said they might talk in vain, but they could not help it. The payments to the shareholders might be 1s. 6d. or 2s. less than par. The Preference shareholders were a little better off than the Ordinary shareholders.

The resolution was then adopted and the proceedings terminated.

The Manchester Edison-Swan Company.

CENTRAL STATION LIGHTING IN MANCHESTER.

An extraordinarg general meeting of the proprietors of the Manchester Edison-Swan Company, Limited, was held on Tuesday in Manchester for the consideration of the question of supplying the electric light from a central station. In a second circular issued to the shareholders the Directors reminded them that if the proposed scheme be carried out it will entail a further call for capital. Mr. V. K. Armitage presided.

The CHAIRMAN said the Directors had called the shareholders together in fulfilment of a promise made at the very first general meeting of the Company, that they should take no step that would involve the raising of further capital without calling the shareholders together, explaining what it was proposed to do, and obtaining their consent thereto. The Directors were now about to make a proposal that would involve the calling up of from 30s. to £2 a share. Hitherto the Company had confined their business to making separate installations. They had made no attempt at a central installation, because the cost of the old system of distributing the electric current through thick copper mains was practically prohibitive. Like every other electric company in existence, for the first few years they lost money steadily, but last year they declared a dividend of 5 per cent. During the six months of the present year they had made profits which would enable them to pay another five per cent. Quite of recent years the system of distributing electricity had materially improved, and now the current could be sent at high tension down thin and inexpensive mains, and could be commuted when it arrived at a house into low-tension mains for domestic purposes. Under these circumstances, the Directors felt it their bounden duty to arrange for the supply of electricity from a central station in Manchester. There were a number of rivals in the field, and if that Company did not take steps to establish a central station in Manchester some other firm would. The Directors, therefore, suggested that a canvass should be undertaken by the Company to see how many people desired to have the electric light in the district they proposed to serve. For obvious reasons he could not enter into the full details of the scheme, but they had been very carefully prepared by Mr. Williamson. They proposed to establish a central station within half a mile of the Royal Infirmary for a maximum of 10,000 lights. They reckoned the cost of laying the mains at £40,000 and the cost of maintenance at £8,000 a year. If they let the whole of these lights at an average charge of 25s. a light that would bring in about £12,500 per annum. If the scheme was agreed to circulars would be issued and canvassers would be sent round to get replies, and if they had a promise of customers for 5,000 lights they would be justified in making a start. They would then try to persuade the Corporation to contract with them for the supply of the light without compelling them to go to Parliament. They would offer the Corporation strong inducements. They were willing to undertake to erect and maintain the station, and to provide a continuous supply of light. As the Corporation sold gas the Directors were willing to give them a royalty on every light they replaced with electric light, or give them a share of the profits at the end of the year. They were willing that the Corporation should lay the mains, and make all connections that involved the taking up of the streets, or that the Corporation should lay their own mains and the Company pay for the use of them, as was the case with the tramway lines. The Company were also willing to limit their profits to 10 per cent., and at the termination of a certain period to give the Corporation the privilege of buying the undertaking for the benefit of the ratepayers. If the Corporation withheld their consent the Company would have to apply to the Board of Trade, but this meant delay and increased expense. He moved:—

"*That this extraordinary general meeting of the Manchester Edison-Swan Company (Limited) approves of the proposed scheme for the establishment of a central electric lighting station in Manchester, and authorises the Directors to raise the requisite capital by making a call or calls not exceeding in the aggregate £2 per share as and when they may be required.*

"*The meeting expresses its earnest hope that the Corporation of Manchester may be induced to give the necessary facilities to enable the Directors to carry the scheme into effect.*

"*That a copy of the foregoing resolution be sent to the Mayor of Manchester and to every member of the Corporation.*"

Mr. I. C. WATERHOUSE seconded the motion.

Mr. WILLIAMSON stated what was being done in Bradford, London, and other places in the way of providing electric light from central stations. He was certain there would be a good demand for the light in Manchester, and that they would have no difficulty in placing from 5,000 to 10,000 lights on terms that would be profitable to the Company.

Mr. CHARLES HOPKINSON said the speculation did not appear to be an attractive one. The risk was very large and the profit limited. He had nothing to say against the scheme as a scheme, and he believed the directors were quite competent to carry it out. It was, however, inexpedient to make themselves too cheap in dealing with the Manchester Corporation.

The resolution was put to the meeting, and carried.

NEW COMPANIES REGISTERED.

ELMORE'S PATENT COPPER DEPOSITING COMPANY (LIMITED)—Registered by Newman, Hays and Co., 31, Abchurch-lane, London, E.C. Capital £200,000, divided into 100,000 shares of £2 each. Object, to purchase, take over, and work the whole of the British patents of Francis Edward Elmore, and all improvements thereunder whensoever made, relating to the treatment and electrical deposition of copper

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.
The best for overhead Telephone and Telegraph Lines,

and other metal, for the manufacture of copper and other metal articles, and to carry on the business of manufacturers of and dealers in copper and other metals. The first subscribers to the company are :—Sir J. H. Morris, 88, Queen's-gate, London, S.W. ; E. J. Carron, Rydal, Surbiton Hill Park, S.W. ; A. Holland, 2, East India-avenue, London, E.C. ; J. P. Beadle, 6, Queen's Gate-gardens, London, S.W. ; J. MacFarlan, Invermay, Wimbledon, Surrey ; G. Smith, West Bank, Lewisham-hill, London, S.E. ; F. L. Rawson, 11, Queen Victoria-street, London, E.C. There shall not be less than three nor more than nine directors of the company, and the first shall be appointed by the subscribers to the Memorandum of Association. Each director shall hold at least 250 shares in the capital of the company. The board of directors, exclusive of the managing director or directors, shall be entitled to a remuneration of not more than £1,500 per annum, together with 10 per cent. of the net profit of the company, after a payment of 20 per cent. dividend per annum to the shareholders.

THE MAXIM-WESTON ELECTRIC COMPANY (LIMITED).—Registered by Gresham and Davies, 12, Old Jewry, London, E.C. Capital £75,000, divided into 500,000 shares of 3s. each. Objects : To acquire and undertake the property and liabilities of the Maxim-Weston Electric Company (Limited) (in liquidation). To light streets, thoroughfares, public places, public or private buildings, manufactories, mines, houses, ships, etc. The first directors shall be John Marks, 113, Great Russell-street, W.C. ; James Gunton Couchman, Southwood, Eltham-road, Lee ; George Herbert Hildyard, 34, Wickham-road, St. John's, S.E. ; John Nathan Klenck, 43, Bishopsgate-street, E.C. ; and Louis Swaby, 23, Churchfield-road, Ealing. Each director shall hold at least 250 shares in the capital of the company. The remuneration to the directors shall be the sum of £1,000 per annum, to be divided amongst them as they may determine.

MINER'S LAMP ELECTRIC LIGHTING COMPANY (LIMITED).—This company was registered on the 12th inst., with a capital of £3,000, divided into 600 shares of £5 each, to acquire a certain invention and letters patent for miners' safety and other lamps and wicks. To carry on the business of a Safety Lamp Manufacturing Company and Electric Light Company in all its branches. Registered without special Articles of Association. Registered office, 71, Albion-street, Leeds. The purchase consideration is £1,000, payable £850 in fully paid shares and the balance in cash.

NEWCASTLE AND DISTRICT ELECTRIC LIGHTING COMPANY (LIMITED).—This company was registered on the 14th inst., with a capital of £50,000, divided into 5,000 shares of £10 each, to supply electricity for lighting and other purposes, whether public or private, in the city of Newcastle-upon-Tyne, or elsewhere in the United Kingdom. The first subscribers are :—The Hon. C. A. Parsons, Elveston Hall, Ryton-on-Tyne ; Sir B. C. Browne, Westacres, Newcastle ; J. D. Milburn, West Jesmond House, Newcastle ; J. B. Simpson, Hedgefield House, Ryton-on-Tyne, coal-owner ; H. C. Harvey, St. John's Chambers, Newcastle-on-Tyne, solicitor ; Earl Crawford, 2, Cavendish-square, London, W. ; A. F. Wade, 108, Victoria-street, London, S.W. ; W. M. Angus, St. John's Works, Newcastle-on-Tyne ; C. W. Spencer, Newburn Steel Works, Newcastle-on-Tyne. Registered without special Articles of Association.

CITY NOTES, &c.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).—At a meeting of the directors of this company, held on Friday last, it was resolved to recommend to the proprietors at the next half-yearly general meeting of the company, to be held on the 1st February next, the declaration of the following dividends :—

1. A balance dividend of 15s. per cent. upon the ordinary consolidated stock for the year ended 31st December, 1888.

2. A balance dividend of 30s. per cent. upon the preferred stock for the year ended 31st December, 1888, both payable on the 2nd February next, less income-tax, to the stockholders registered on the books of the company on the 14th inst.

After paying the foregoing dividends there will be an estimated balance of £1,325. 13s. to be carried forward to the next account. The above dividends, together with those already paid, will amount to £1. 12s. 6d. per cent. on the ordinary consolidated stock, and £3. 5s. per cent. on the preferred stock for the year 1888. The register of transfers of the company will be closed from 18th January to the 1st February, both days inclusive.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended January 18th amounted to £5,077.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED)—At a meeting of the board of directors of this company held on Wednesday the audited accounts for the half year to December 31st last were submitted, and it was resolved, after providing for the dividend on the Preference shares and placing £4,000 to the reserve fund, to recommend a distribution on the Ordinary shares at the rate of 9 per cent. per annum, free of income-tax, leaving £1,308 to be carried forward to the current half year's account.

EASTERN TELEGRAPH COMPANY (LIMITED).—Coupons on the Five per Cent. Debentures of this company due February 1st, will be paid on and after that date at the banking house of Messrs. Glyn, Mills, Currie and Co., 67, Lombard-street, E.C.

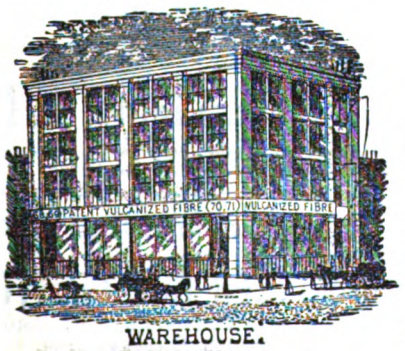
WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this company for the week ended January 18, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,195.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The traffic receipts for the half-month ended December 31st, 1888, were £2,359, as compared with £2,805 in the corresponding period of 1887 ; and for the half-month ended 15th January, 1889, were £2,381, as compared with £2,676 in the corresponding period of 1888. The September traffic, estimated at £4,513, realised £4,540.

BELL'S ASBESTOS COMPANY (LIMITED).—The report of the directors of this company for the year ended December 31, 1888, states that the net profit from the ordinary trading of the company, after making all needful deductions, including depreciation of machinery and bad debts, was £23,429, and the net profit from the company's asbestos estates in Canada was £10,992, making a total of £34,421, from which the directors write off the whole of the preliminary expenses account, namely, £837 ; and under the terms of the Articles of Association they place £5,000 to reserve fund, thus leaving £28,585 for appropriation. They recommend the payment of a dividend of 15s. per share, free of income-tax, which, with the interim dividend paid in July last, makes a total distribution of 22½ per cent. for the year, and the payment of the bonus, £2,250, to the managing director and directors, in terms of the Articles of Association, carrying forward the balance of £3,835.

ELMORE'S PATENT COPPER DEPOSITING COMPANY.—Elmore's Patent Copper Depositing Company (Limited) has been formed to acquire and work the British patents for the discovery made by Messrs. F. Elmore and A. S. Elmore for manufacturing copper articles direct from rough copper bars, which does away with the processes of melting, rolling, forging, drawing, &c., and the present costly and laborious methods of manufacturing copper articles. It is claimed that by this process (see *The Electrician*, March 2nd, 1888, p. 436) articles are produced at a low cost, hitherto unknown, and that the invention is destined to take the same leading position in the copper industry which Bessemer's process has done in that of iron and steel. Distinguished professional men and leading technical experts are shown to have given high opinions of the invention, and to have recognised the process as entirely novel and practical, and calculated to largely supersede the present methods of working copper. Works in Sheffield have been secured by the company, and it is estimated that the machinery can be completed and the factory commence profitable work in about three months. The patentees have agreed to serve the company as managers for six years, at a fixed joint remuneration of £550 per annum, and a further sum of £100 between them for every 5 per cent. dividend paid to the shareholders. The company's profits will be obtained from licenses on royalties to the trade for the articles at present manufactured by them, and the earnings from the factory, which, it is estimated, will amount to over £100,000 per annum, equal to a profit from this source alone of over 70 per cent. per annum upon the capital. The amount to be paid by the company is £53,400 in cash, and £46,600 in fully paid shares, and the capital will be £200,000 in 100,000 shares of £2. It is stated that over 165,000 shares were applied for, against 43,600 to be allotted.

THE NON-CONDUCTOR OF ELECTRICITY.



WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

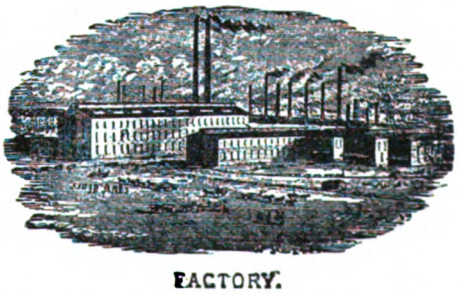
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb. ; HARD, 2/3 per lb.



FACTORY.

ENDLESS TELEGRAPH PAPERS.

(As supplied by Waterlow and Sons, limited, to Her Majesty's Postal Telegraphs.)

These Papers are kept in stock in large quantities, and can be cut to any width for the **MORSE, WHEATSTONE, HUGHES,** and other machines; also the **RECORDER** Printing Paper, as used on the various Electric Automatic Printing Instruments.

COLLOTYPE PRINTING.

High class Reproductions in Facsimile of Monochrome Drawings, &c., specially useful for the Illustration of Trade Catalogues.

PHOTO-INTAGLIO ENGRAVING ON COPPER; PHOTO-ZINC ETCHED BLOCKS.

Photo-Lithography and Photo-Engraving and Printing in all its branches.

WATERLOW & SONS, LIMITED,

27, GREAT WINCHESTER STREET, LONDON, E.C.

VULCANITE

SHEETS, RODS, TUBES, CELLS, &c., for Electrical Purposes,
MANUFACTURED BY
THE NORTH BRITISH RUBBER CO., LIMITED.
EDINBURGH; LONDON, 57, Moorgate-st.; MANCHESTER, 6, Charlotte-st., LIVERPOOL, Cereal-court; GLASGOW 106, Buchanan-street.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 559.—Vol. XXII. FRIDAY, FEBRUARY 1, 1889. Price Fourpence.

NOTES.

At the end of the revised report of Sir William Thomson's Presidential Address will be found an appendix containing the formulæ from which the distribution of alternating currents in wires of different sizes may be calculated. Sir William also supplies a table which will greatly facilitate the calculation in the particular case where the current has 80 complete periods per second.

The extent of the deterioration to which copper is liable under the long-continued action of electric currents is a question upon which the evidence is somewhat contradictory, but it is at least certain that some samples have deteriorated to an alarming extent. We are therefore glad to learn from *La Lumière Electrique* that M. Firmin Larroque is carrying out a systematic investigation on this question, and that his experiments have already been four years in progress. M. Larroque has examined some wire taken from a lighthouse, which had been in use over twenty years; he found that its surface was pulverulent, it was easily broken by a hammer, and its texture was granular; in fact, it presented many of the properties of ordinary electrolytically-deposited copper. In another case in some wire taken from a secondary of a Ruhmkorff coil, and which had therefore been subjected to alternating currents, the degradation was even more marked. The coil could not be unwound without repeated fracture, and its resistance had increased by no less than 30 per cent. It is somewhat remarkable that in this case also its texture resembled that of electrolytic copper. M. Larroque's experiments are being conducted in the following manner:—He has taken thirty-six strips of copper each ten milliimetres in width and three millimetres in thickness (the length is not given). One half are bent into spirals and the other half into zig-zags, and some are annealed and some hard-drawn. They are suspended from a frame, and kept stretched by weights of 10 grammes attached to the lower ends. Each strip is traversed by a current varying from ·5 ampere to 2 amperes, which has been maintained constant since the commencement of the experiment. The current is alternating (at the rate of 75 reversals per second) in one set, and continuous in another. From time to time an exact measurement of the elongation of the spiral is obtained, and this is taken as a measurement of the loss of elasticity of the metal. For the first eight or nine months no effect was observed, but after that a slow elongation became manifest. The amount of elongation in the different specimens increased with the current, and was more marked with the alternating than with the continuous currents.

The fact which thus seems to be fairly well established that under the action of long-continued currents the molecular structure of copper tends to assume the condition of electrolytically deposited metal would seem to point to the use of conductors built up by the same process, in which case we might assume that there would be no further tendency to an alteration of texture. But it unfortunately happens (unless we are mistaken) that the electrolytically deposited wire at present in the market has its fibres laid transversely and not longitudinally, so that it would not possess any advantage in this particular. We shall be glad to be corrected if we are wrong in this assumption; and in any case it is scarcely possible as yet to say what amount of practical importance attaches to the question.

Prof. Brackett, of Princeton College, in an interesting address delivered before the New York Electric Club, spoke hopefully of the problem of obtaining light without heat. He is going to experiment with polarised light in order to see if it is possible to evoke electro-magnetic waves of high-periodicity in a conducting medium—so that he proposes to attack the problem in the first instance from the rear. In a passage which is perhaps intentionally obscure Prof. Brackett intimates his opinion that "we must get something that is not a conductor in the ordinary sense," and he sees "very hopeful indications" in the known properties of selenium.

In addition to Prof. Forbes's valuable Paper on "Electricity Meters," our readers will also find in the present issue a description of the Hookham meter, which seems likely to play an important part in central station work. It is one of the simplest and also one of the most ingenious meters which has yet come under our notice, and is additionally interesting as being one of the very few instances in which Foucault currents are made to do useful service. The meter is already at work not only at Leamington but also in Liverpool, where it is used by the Liverpool Electric Supply Company. We may add that this meter bears some resemblance to an instrument of the same class patented by Messrs. Siemens some years ago; but we have not heard that the latter has ever been brought into use.

In the discussion on Prof. Forbes's Paper at the Society of Arts last week, the question of the most suitable candle-power for domestic lighting evoked considerable divergence of opinion. With Prof. Forbes's strong condemnation of the practice of running 16 candle-power lamps at 8 or 10 candles everyone will emphatically agree, and, indeed, we believe that the extent to which this is now being done in the West End is injuriously affecting the immediate prospects of electric lighting—at any rate in that neighbourhood. Anything better calculated to provoke disgust than the "red hair-pin" style of illumination (?) it is difficult to imagine. On the other hand, we may place reliance on the experience of Mr. Crompton and others, who find that for private houses lamps rated at 8 candle-power and burnt at 8 candle-power fulfil the public requirements to a very large extent. It is not the policy of the Electricity Supply Companies to run up the bills of the consumers, and for passages, halls, offices and rooms of medium size, there can be little doubt that 8 candle-power lamps are amply sufficient for all practical purposes. For larger rooms, where several lamps are required, it becomes a question of effecting the best distribution of light, and each case must be settled on its own merits. We would also endorse Mr. Preece's protest against the rating of dynamos or central stations in terms of lamps, unless the number of watts be stated. Mr. Preece proposes that a "lamp," unless otherwise specified, should be a lamp of 50 watts. This is a suggestion which will probably commend itself to most people.

The West Brompton Station of the House-to-House Electric Light Supply Company was opened with some *éclat* on Thursday week. So far as we have had an opportunity of judging it appears to be a very creditable piece of work, and one of which the company has every right to be proud. We are sorry not to be in a position to criticise the details, but the fact is that—doubtless by some oversight—the visit of the technical press was made concurrent with that of the general public, who were present in great force. We mention the circumstance less by way of complaint than as an explanation of the fact above mentioned. The account on another page is abstracted from a pamphlet with which the visitors were presented.

On another page will be found some details of the important contract which Messrs. Mather and Platt have entered into with the City and Southwark Subway Company, for the equipment and working of the line from Stockwell to London Bridge. We are extremely pleased that an opportunity has thus arisen which will enable Dr. Ed. Hopkinson to show what electric traction, under favourable circumstances and in competent hands, is capable of accomplishing. As to the complete success of the undertaking we have no misgiving whatever, and there is also little doubt that it will impart a most valuable and much needed impetus to electric railway work in this country.

If the time should ever arrive when the apparition of a horse in the business quarters of our great towns will have become a comparatively unfamiliar spectacle, then we should be sincerely grieved if the finger of scorn could be pointed at the pages of *The Electrician* in which the possibility of such a result had been denied. We desire, therefore, to state that we have not committed, and do not now commit ourselves, to any such denial. But the question which has of late been forced upon our attention is whether in the present state of the art of electric traction by batteries it is practicable to employ this means for the propulsion of vehicles upon ordinary roads, and to do so upon a strictly commercial basis. This problem has for some time engaged the attention of a well-known electrical engineer, Mr. Radcliffe Ward; and as the result of a series of experiments extending over several months, during which his "electric omnibus" has traversed some 200 miles over the London streets, Mr. Ward is of opinion that he is entitled to answer the question in the affirmative. Now it will scarcely be necessary on our part to state that we should like nothing better than to be convinced of the soundness of a scheme which promises greatly to extend the domain of the commercial application of electricity; and in the event of success we should desire to be amongst the first to congratulate Mr. Ward upon a very noteworthy achievement. But we must reluctantly confess that, after having enjoyed opportunities of becoming acquainted with the details of the project, and having taken time to consider the question to the best of our ability and in all its bearings, we have not succeeded in convincing ourselves that it ought to receive such support as for many reasons we should have wished to be able to afford.

It seems scarcely necessary to recapitulate in detail every difficulty or objection which arises in the contemplation of a scheme of this character. From the commercial point of view we have to inquire how it comes to pass that a mode of traction which has not yet proved an indisputable success when applied to vehicles running on rails can be expected to give satisfactory results under the far more exigent conditions of ordinary street traffic. From the technical point of view we want to be assured that the weight, durability and rate of discharge of the batteries, the arrangements for recharging, the method of driving and steering the vehicle, and other matters of detail which readily suggest themselves, have been brought to the necessary degree of perfection. (Here we must, in justice to Mr. Ward, remark that in some of these points his arrangements seem to be of a specially promising character, and, at least, display considerable ingenuity.) But there is yet another point of view on which we should be doing wrong to maintain silence, and where the only conclusion at which we are able to arrive is one of an adverse character. Under existing circumstances would the admission of electrically-propelled vehicles upon our ordinary streets be consistent with due regard to the public safety? Remembering that the driver will have to handle steering gear as well as the starting, stopping, and slowing levers, remembering also that the addition of batteries and motors will probably increase the dead weight to at least three times that of existing vehicles of the same description, we are unable to see our way to accept the responsibility which would be entailed by advocating their introduction. On the other hand, it is only fair to give Mr. Ward the credit of having

Digitized by Google

conducted his experiments so far without any accident—save one of a humorous description for which he was not personally responsible. And again, we do not say that the objection applies so seriously to slow-moving vehicles, such as trolleys and dust-carts (to both of which Mr. WARD hopes to apply the method); only in this case the technical difficulties, owing to the strain on the batteries, motors, and gearing, are very great. Finally, there is the legal question. Mr. WARD is advised that there is no existing law interfering with the project, and that the red-flag clause does not apply. He is, however, very properly desirous that the subject should be placed under the control of the Board of Trade. We cannot avoid a feeling of regret that Mr. WARD should not have devoted his very considerable talent and energy to a cause, such as that of tramcar traction, in which he would not have been encumbered with the serious difficulties which we have felt it our duty to name.

Restoration of the Falmouth and Bilbao Cable.—The cable of the Direct Spanish Telegraph Company between Falmouth and Bilbao is now repaired.

"Modern Views of Electricity."—The papers on "Modern Views of Electricity," by Prof. Oliver Lodge, which have been appearing in *Nature*, will soon be published as a volume of the "Nature Series."

Patent Litigation in the States.—The action which M. Camille A. Faure has brought against the Cowles Electric Smelting Company for infringing his electric smelting patents is now proceeding.

Liverpool Tramways.—The Liverpool Tramways Company have decided, as soon as possible, to abandon horse-power in favour of some form of electrical or mechanical traction. They are open to suggestions on this point.

St. Martin's-in-the-Fields Vestry.—At a meeting of this Vestry on Thursday last week consent was given to an application for a license authorising the House-to-House Electric Supply Company to supply electricity within the parish.

St. Mary Abbotts, Kensington.—The local authorities of the parish of St. Mary Abbotts, Kensington, have decided to apportion to the House-to-House Electric Supply Company a district which is bounded by Cromwell-road, Fulham-road, and Onslow-square.

Fleming's Practical and Useful Diary for 1889.—This little publication, issued by Messrs. Thos. Fleming, Son and Co., of Halifax, manufacturers of machine-bands, fully justifies its title of practical and useful, containing, as it does, an immense amount of valuable information about belts of all sorts.

London Central Subway Railway.—A meeting will be held at the Holborn Town Hall this day (Friday) at 8 p.m., when the system proposed to be adopted in connection with the above railway will be explained, and a model exhibited. Those of our readers who are interested in the scheme will doubtless be welcomed.

Ipswich.—At the fortnightly meeting of the Paving and Lighting committee, held on Friday last, the clerk laid before the committee a copy of the license for which Messrs. Laurence, Paris and Scott proposed to apply to the Board of Trade. He suggested that it should be referred to someone conversant with the matter.

Hove.—At a special meeting of the Hove Commissioners on Saturday last, it was decided to oppose the Provisional Order sought by the Brighton and Hove Electric Light Company (Limited). One of the reasons assigned for this decision was that "the science of electric lighting was not sufficiently advanced to warrant the grant to any company of statutory power to break up the public streets."

Islington Vestry.—The Special Committee appointed to consider the applications of the London Electric Supply Corporation and the Metropolitan Supply Company, asking for the Vestry's assent to their application for Provisional Orders, recommended that the clerk be directed to lodge objections to such Provisional Orders with the Board of Trade, in order to secure a *locus standi*.—The adoption of the report was carried.

The "Industries" Motor Competition.—A correspondent writes to us: "Can you or any of your readers give information about the prize competition for the design of a 10 horse-power electric motor which was instituted by your contemporary *Industries* at the end of 1886? Have the judges come to any definite decision? And why are the designs of the unsuccessful competitors refused to be returned at this date, after more than two years' detention?"

St. Saviour's (Southwark) Board of Works.—At a meeting of the St. Saviour's (Southwark) Board of Works on the 23rd inst. the General Purposes Committee reported that they had considered the several notices and applications under the Electric Lighting Acts, and were of opinion that no opposition should be offered to the schemes for lighting the district by means of electricity, but that representations should be made to the Board of Trade that all wires in connection therewith should be laid underground.—The report was adopted.

Liverpool Electric Supply Company.—On Tuesday last a deputation, representing the Liverpool Electric Supply Company, waited upon the Watch Committee of the City Council and endeavoured to procure their assent to the Provisional Order which the company intend to seek during the forthcoming session of Parliament. In spite of an unusually protracted consultation it was found impossible to come to terms, and the practical result, therefore, is that the Watch Committee will refuse their assent to the company's application.

Metropolitan Board of Works.—At a meeting of the Board last week, Mr. Hughes, M.P., brought up the report of the Parliamentary Committee, which set forth that they had considered the electric lighting provisional orders referred to them by the Board and recommended that the solicitor should be instructed to communicate with the Board of Trade, requesting further time to submit any necessary observations and such revisions to detail as might be desirable to meet the objections of the Board. The recommendation was agreed to.

The Manchester Telephone Staff.—On Friday, the 25th inst., the Manchester staff of the Lancashire and Cheshire Telephonic Exchange Company (Limited), held their fifth annual *soirée* at the Manchester Athenæum. There was a large attendance of officials and friends, and a most enjoyable evening was passed. As in each previous year, Mr. Joseph Poole (chief electrician to the company) made an able and popular "M.C.," and his efforts were well supported by the stewards, Messrs. R. F. Beer, T. J. Clark, W. G. Heys, A. Hodgkinson, and E. Whitworth.

Newcastle.—A meeting of the sub-committee of the Newcastle Town Improvement Committee was held on Wednesday last week to consider the applications made, one by Messrs. Leadbitter and Harvey, and the other by Messrs. Watson and Dendy, on behalf of two separate companies for the concurrence of the committee in their applying to the Board of Trade for powers to supply the electric light in Newcastle. Representatives from the respective promoters were present, who explained what it was intended to do. The feeling of the committee was favourable to the consent of the Corporation being given, as long as there was no monopoly created, and provided the wires were placed underground. The matter will be further considered at a special meeting.

A Statue to Ohm.—A meeting was held yesterday afternoon in the Royal Society's meeting room to appoint a committee, with a view of obtaining subscriptions in aid of a proposed memorial to Ohm. The 16th of next March will be the hundredth anniversary of the birth of George Simon Ohm, and in view of the near approach of the centenary of the birth of a man who has done so much for electricity a committee has been formed in Germany to promote the erection of a statue of Ohm in Munich, the capital of his native state, Bavaria, and the city in which the latter part of his life was spent as professor of physics in the university. The co-operation of those who in other countries take an interest in this design of honouring

Digitized by Google

the memory of a benefactor of his race has been invited by the German Committee.

Gas Mains as Electrical Conduits.—The problem of conveying telephone and electric lighting wires underground in large cities has received a partial solution in New York, where for the last few years a telephone conductor has been run inside a gas main, between the gasworks of the Consolidated Gas Company, at 99th and 111th-streets. The conductor enters the gaspipe by a stuffing-box, made gas-tight by plaster of Paris. The wire is carried by glass insulators fixed in the roof of the pipe. The length of the circuit is over half a mile, and it has been in continual use. Owing to the success of this experiment a series of new mains have recently been supplied with telephone cables serving for the use of the gas company. The experiment tends to show that the disused mains of a gas company might profitably be employed for running the wires of an electric lighting company underground.

Lambeth Vestry.—At a meeting of the Lambeth Vestry on Thursday evening last week a letter was read from Messrs. Deacon, Gibson, and Metcalf, enclosing copy of a draft Provisional Order deposited with the Board of Trade by the London Electric Supply Corporation, and asking the Vestry's assent to the same. Messrs. Bircham and Co. wrote on behalf of the Metropolitan Electric Supply Company, asking for similar assent. A further letter was read from the Wandsworth District Board of Works, inviting delegates to a conference on the question of electric lighting in South London, to be held in the hope of securing, by combined action, such amendments in Provisional Orders as were calculated to fully protect the interests of the public generally and the road authorities. These communications were referred to the Electric Lighting Committee for consideration and report.

Lithanode.—Mr. Oswald Swete, of the Mining and General Electric Lamp Company, writes as follows:—"I have been asked by our consulting electrician, Mr. D. G. FitzGerald, to forward you some samples of 'lithanode,' which I now do. Hitherto, by the policy of other companies who previously owned and worked the patents, lithanode has been most jealously guarded from the public gaze, and no samples have been issued for experimental purposes to the public. My directors, however, have decided to issue such samples to anyone who does not mind the trouble of applying for the same, enclosing a stamped addressed label. You will see by the small plate one method of connection, and I think the best, Bunsen battery clamps with platinum foil, however, may be used, also carbon contacts. One ounce of this material will give one ampere-hour discharge. The plates can be cut easily by the aid of a fret saw. With zinc as a cathode, the E.M.F. is 2·375 per cell; in an electrolyte such as dilute sulphuric acid sp. gr. 1·170."

St. George-the-Martyr Vestry.—At a meeting of this Vestry on the 22nd inst. Mr. Sinden moved the adoption of a report from the Roads Committee, recommending that this Vestry dissent from the granting of a Provisional Order by the Board of Trade to the London Electric Supply Corporation (Limited) for the supply of electricity in this parish, under the Electric Lighting Acts; that this Vestry assent to the granting of a license by the Board of Trade to the House-to-House Electric Lighting Company (Limited), authorising that company to supply electricity within this parish. Mr. Sinden said the Committee objected to the first application, because a Provisional Order would give the company privileges in the parish for forty-two years. The second company asked for a license which would only extend over seven years. A long discussion ensued. The first recommendation was adopted, but the consideration of the second recommendation was deferred until the next meeting of the Vestry, in order that the representatives of the House-to-House Company might be in attendance.

Dublin.—A correspondent writes from Dublin as follows:—"In Dublin considerable interest is at present being aroused in connection with electric lighting. At a meeting of the Municipal Council last Monday it was all but unanimously resolved—there being only one dissentient—to apply to the Board of Trade for a license for *private* lighting. It will be remembered the Council have already acquired a license for *public* lighting, and seeing that greater advantages would necessarily attach to the privilege of dealing with the question in a general way, the local authorities are acting wisely in thus amending their position. Meantime, the Dublin Alliance Gas Company have put down a new installation during the year, and are at present lighting several of the large business houses throughout the city with both arcs and incandescents and are offering inducements to new customers. There are also several isolated installations working satisfactorily in Dublin, notably those at Messrs. Guinness's Brewery, Messrs. Findlater's, Chapelizod Distillery Company, &c., &c., and perhaps the most complete and successful installation in Dublin is that at the offices of the Irish *Times*, which was put down five years ago, and has been working continuously since under the superintendence of Messrs. J. K. Fahie and Son, electrical engineers of Dublin, giving the greatest possible satisfaction to the *employés*, especially the compositors, whose work is carried on during the greatest part of the night."

Electric Traction in Coal Mines.—In a Paper read by Mr. A. W. Sheafer before the Engineers' Club of Philadelphia we read "that the Lykens Valley Coal Company, at its mines in Dauphin County, Pa., has introduced the electric locomotive with, it seems, considerable success. The road here is 6,300ft. long, supplied with a third rail carried along the side of the gangway. The average load is 20 cars per trip, or 850 tons per day, equivalent to 1,040 mile-tons per day. The Union Electric Company, which furnished this plant, gives the daily expenses of running the locomotive as $5.71, or a cost per mile-ton of 0.67 cent. This, they claim, can be reduced by the use of better graded roads and heavier mine waggons to 0.40 cent. per mile-ton. The writer, in a former Paper, gave the relative costs of mule and steam locomotive haulage at Kalmia Colliery, and now introduces them here for comparison with electricity as follows:—

	Mule.	Steam.	Electricity.
Cost per ton-mile.....	1·82 cent.	0·60 cent.	0·40 to 0·67 cent.

It should be borne in mind that the cost as regards mule and steam power are based upon the prices of 1882, while the estimate for electricity is for 1887; consequently, the comparison is not entirely a just one; but it is made to show that we may expect under favourable circumstances electric haulage to at least do the work required as cheaply as steam power, and with less attendant danger to the mine."

Sir John Pender and the Glasgow Telegraph Staff.—The following is the reply from Sir John Pender to the address from the telegraph staff which was forwarded to him on the 21st inst.:—

"18, Arlington-street, London, S.W.
"22nd January, 1889.

"Dear Sir: I am in receipt of your favour of the 21st inst., enclosing an address from the Glasgow postal telegraph staff. I value it very much, because it is an evidence on the part of those who can best understand the importance of the work of the great value of the submarine system, and I am very pleased to learn from those who have signed the address that they approve of the manner in which the submarine system is conducted.

"It has been my ambition, and the ambition of those associated with me, to do full justice to the telegraphing public, and also to the *employés*, in whose hands the proper execution of the great work lies.

"Submarine telegraphy has been one of the remarkable combinations of science and commercial enterprise of the age. I hope it will ever remain non-political, and that in its development it will continue to bind the nations of the world more closely together, particularly our vast empire, of which we all ought to be so proud, and which it ought to be our ambition to maintain.

"Thank all the subscribers for me, and assure them of my sympathy and interest.—Yours faithfully,

(Signed) "JOHN PENDER

"D. Mackie, Esq., Accounts Branch,
Post Office, Glasgow."

The Proposed Electric Traction on the Metropolitan Railway.—In the report of the Metropolitan Railway Company which has just appeared the following reference is made to the proposed electric traction experiments:—"The directors regret that the Electric Traction Company have not been able to complete their arrangements for the experimental working, by an electric-power locomotive, on a section of your railway. The

Digitized by Google

following letter from the chairman of the Traction Company has been received :—

"The Electric Traction Company (Limited),
"New Broad-street House, London, E.C., 31st Dec., 1888.
"The Board of Directors, Metropolitan Railway.

"Gentlemen : In reply to your inquiry respecting the progress of the electric locomotive for your company, I have to say that the difficulties which were spoken of in your last report, which principally concerned the working of the vacuum brake without the use of steam, though intractable for a considerable time, have now been overcome. The whole matter is in active progress, and has made considerable advance since the last report.

"The Electric Traction Company wish it to be explained that an erroneous belief appears to be entertained that they propose to suggest traction by means of accumulators for ultimate use on the Metropolitan line. This is not the case. The use of accumulators is for a temporary service only, and is rendered necessary by circumstances connected with the traffic, which will disappear when electric traction is adopted on the underground railway.

"I am, Gentlemen, yours faithfully,
"(Signed) BURY,
"Chairman, Electric Traction Company."

The City.—As we mentioned last week, the report of the Streets Committee of the City Commissioners of Sewers was ordered to be printed and circulated. The draft conditions under which tenders are to be invited for supplying electric lights for the City have now been issued. The main thoroughfares and public streets of the entire area of the City are to be lighted by electricity, and, for the sake of convenience, are to be divided into three districts (west, central, and east), the contractors being at liberty to tender for either one or two of the districts or for the entire City. The existing system of gas lighting will not be interfered with, but the contractor will be allowed in certain cases, with the consent of the engineer, to use any of the existing gas columns or brackets. The electric lamps must be fixed on such standards as the commissioners may approve. It is to be obligatory on the companies to lay all wires and conductors beneath the public way. The whole of the main thoroughfares are to be primarily lighted ; the companies to state the period at which the lighting of the thoroughfares will commence, and when it will be extended to the remaining streets. One condition is that when the profits have reached a cumulative dividend of 10 per cent. the surplus shall be divided equally between the contracting company and the consumers. The Commission will consider a report to this effect and the conditions of the proposed contract at their next meeting, and, if adopted, tenders will be advertised for on the basis thus laid down.

The New Electric Light Works of the Elwell-Parker Company.—The directors of the Elwell-Parker Electric Light Company (Limited), Wolverhampton, propose to erect entirely new works in order to meet their growing trade, and lately they have acquired twelve acres of land adjacent to Bushbury Junction, on the main line of the London and North-Western Railway Company. It is only some seven years ago that Mr. Elwell and Mr. Parker started the works in Commercial-road with the object of making a speciality of electric lighting apparatus. Two years afterwards Mr. Charles Moseley, of Manchester, and a few friends joined the firm, and the present company of Elwell-Parker (Limited) was formed on the 3rd September, 1884. At that time not more than thirty hands were employed on the works. At the present time the firm have an order on hand to supply a central station for giving 20,000 lights in Melbourne, and have just completed a contract for dynamos for the central station for the House-to-House Company in South Kensington. A year ago they sent out one of their electric cars to Sydney, where it was thoroughly tested, and it has now been adopted for use on the Ballarat tram lines. Since then a complete tramcar plant has been sent out to Melbourne. In the manufacture of accumulators the firm have been exceedingly busy for years, and they are now using from ten to twelve tons of lead a week in the output of these articles. As the business expanded the number of hands in the employ of the firm grew, until to-day there are 500 at work. About eighteen months ago Mr. Elwell left the firm, and a year ago, on the death of Mr. Charles Moseley, his brother, Mr. Joseph Moseley, assumed the position of chairman of the company.

St. George's (Hanover-square) Vestry.—At a meeting of this Vestry on the 24th inst., the Electric Lighting Committee submitted a long report, which showed that the following companies were applying for Provisional Orders to supply the parish with the electric light :—The London Electric Supply Corporation (Limited), Metropolitan Electric Supply Company (Limited), Westminster Electric Supply Company (Limited), and the Chelsea Electric Supply Company (Limited). The report recommended that the application of the latter company should be refused, and, if necessary, opposed before the Board of Trade; that the matter be referred back to the committee for negotiation with the three other companies, with a view to altering their drafts in certain particulars ; and that the Vestry authorise the committee to instruct Messrs. Caprons and Co., solicitors, to oppose all or any of the four schemes, as might appear expedient. The suggested alterations included binding the companies to complete any works within eighteen months from the date of the order, instead of two years ; that, provided a company fail to perform its obligations to light any place, a money penalty should be inflicted rather than a revocation of its order as to that particular place ; that the quality of the lighting should be subject to the inspection and superintendence of the County Council ; and that deposits of £500 should be made to answer damages by works which might be begun and never continued. Such a deposit the committee would not ask for in the case of the London Electric Supply Corporation, because it had valuable work in that parish and elsewhere, and was thoroughly responsible. The Metropolitan and Westminster Companies were not in any such position, and it was thought prudent to require a deposit from them. The adoption of the report and recommendations was agreed to unanimously.

The Thomson-Houston Electric Company.—The handsome and attractive volume recently issued by the Thomson-Houston Electric Company, of Boston, U.S.A., is another addition to that style of catalogue which the Americans have made so peculiarly their own. The book before us contains some 90 pages, numerous and well-executed engravings, besides clear and terse descriptions of the various Thomson-Houston apparatus. Anything approaching technical detail is carefully avoided ; to such an extent, indeed, has this feature been carried that in the case of the Thomson-Houston transformer we are only permitted to see back and front views of the external casing. However, the catalogue is just what the public requires ; the fine illustrations and plain English descriptions preparing the ground for price-lists and technical details. It seems to us that many of our large English firms might do well to imitate this artistic method of imbuing the public with a proper sense of the value of the electric light. The volume appropriately commences with three cuts depicting the Thomson-Houston factory as it was in the years 1882, 1886 and 1888 respectively, and the growth of the factory has apparently been commensurate with the growth of the system. In January, 1884, there were 2,478 arc lamps running on the Thomson-Houston system. In January, 1888, this number had risen to 36,936 arc lamps, and 74,425 incandescent lamps had to be added. By January, 1889, these totals were respectively 52,000 and 97,067, an increase of over 13 per cent. in each case. We are glad to note, moreover, that nearly 60 gas companies are working stations on the Thomson-Houston system. On page 25 we notice a remarkably good illustration of the Thomson-Houston "Controller Magnet and Regulator." Several pages of engravings of various pattern Thomson-Rice arc lamps come next, and amongst these a form of lamp for use in "low-studded" mills, which possesses the usual good features of the ordinary lamp with the additional advantage of being only 27 inches long. We come next to small search lamps intended for use on board yachts and ships of the mercantile marine, which are made to give from 2,000 to 6,000 candles. On page 49 a new type of Thomson-Houston dynamo for incandescent lighting, with single horse-shoe vertical magnets like the Thomson-Houston meter, is Illustrated. The rest of the book is taken up with descriptions of the Thomson-Houston compensator system, alternating current dynamo, and automatic cut-outs for incandescent lamps run on the multiple series system, the concluding pages being devoted to engravings of various model stations.

ELECTRICAL TRACTION ON THE CITY OF LONDON AND SOUTHWARK SUBWAY.

The method of construction and the system of working of the City of London and Southwark Subway mark a new departure in the methods of communication in our large towns, and will probably afford a complete solution of the problem of underground railways. The subway consists of two tunnels, each 10 feet 6 inches in diameter, formed of segmented cast-iron plates. It extends from the Stockwell terminus at Clapham-road, by the Oval and "Elephant and Castle" at Newington, and then under the Thames to the City terminus at King William-street, the total length of each tunnel exceeding three miles. There will be stations at the Monument, King William-street, Great Dover-street, the "Elephant and Castle," the Oval, and at Stockwell.

As the method of construction, which is entirely novel, has been already frequently described, we need not allude to it more particularly now, but it is only quite recently that the system of traction to be adopted has been finally decided. The original Act of Parliament specified that the traffic should be worked by means of carriages propelled upon the system of the cable tramway, but about a year ago the success of the Bessbrook and Newry Electrical Tramway and other similar undertakings led the directors to consider the adoption of electrical working, and they entered into communication with Messrs. Mather and Platt, of Manchester, on whose behalf Dr. Edward Hopkinson, the managing partner of their electrical department prepared a detailed and elaborate scheme. The matter was under discussion for some months, and finally tenders were invited from the most eminent electrical engineering firms. The result has been that the scheme of Messrs. Mather and Platt has been adopted in its entirety, as affording a perfectly satisfactory and feasible solution of the problem, and a contract has been placed with them for the carrying out of the entire work. The generating plant will be placed at the Stockwell terminus, where boiler and engine plant of over 1,000 horse-power will be erected, and three large Edison-Hopkinson generating dynamos. The current will be conveyed by a lead-covered cable throughout the whole length of the line, and Dr. John Hopkinson's system of overhead conductors will be adopted for conveying the current to the locomotives. This system has proved a great success on a small scale at Bessbrook, and is particularly well adapted for such an undertaking as the subway. There will be 14 electrical locomotives, each capable of developing 100 horse-power, which is sufficient for moving a train containing 100 passengers at 25 miles per hour, and for providing the great power required for starting rapidly. The trains will run at intervals of three minutes, and each consists of three cars. In addition to the plant required for electrical traction Messrs. Mather and Platt's contract includes the lighting of the trains and of the stations, and of the hydraulic lifts and approaches.

The experience gained by Dr. Edward Hopkinson on the Bessbrook and Newry line, which, though on a much smaller scale, is still of the same character, and which has proved a most unqualified success, has solved many difficulties in connection with electrical traction, and will be of great value in the present undertaking.

Mr. James Henry Greathead is the engineer of the Subway, to whose designs the entire works have been constructed; Sir John Fowler and Mr. Benjamin Baker are the Consulting Engineers, and Mr. Spagnoletti the Consulting Electrician.

We append the following extract from the report of the Subway Company which is to be submitted to a meeting of the shareholders on February 12th:—

In accordance with the resolutions passed by the shareholders at the last half-yearly meeting, the Directors have devoted a large amount of attention to the question of the best method of electrical haulage, suitable for efficiently working the traffic upon this line, and they invited proposals from several of the chief electrical manufacturers. After a very exhaustive examination into the details of the several different proposals, your Directors, acting under the advice of the Company's engineers, and aided by the valuable assistance of Mr. C. E. Spagnoletti, an experienced electrical engineer, have entered into a contract for the installation of the necessary machinery and plant with the well-known engineers, Messrs. Mather and Platt, of Manchester, the electrical department of whose business is under the immediate direction of Dr. Edward Hopkinson, who has had exceptional experience in electric traction.

It is with much pleasure that your Directors are enabled to report the satisfactory conclusion of their investigations upon this most important subject. The contractors have undertaken to provide the power necessary to run a three minutes' service from each station at a greater average speed than that now attained on the Inner Circle of the Metropolitan Railways, and they also guarantee for a period of two years the cost per train mile at a considerably lower rate than if steam locomotives were used. Your Directors have the fullest confidence that these provisions will be duly carried out, and will result in the establishment of a system of underground conveyance for the metropolis of an exceptionally convenient character, and worked at such a cost as will give a satisfactory return to the shareholders. The electrical power provided includes also the lighting of the trains and stations.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

SIR WILLIAM THOMSON'S PRESIDENTIAL ADDRESS.*

"Electricity, Ether and Ponderable Matter."

(Concluded from page 334.)

But now there is another line of thought in connection with this subject, and that is the elastic solid idea. Will you allow me to read a very short statement which was published in the *Cambridge and Dublin Mathematical Journal* for the year 1847? It is dated Glasgow University, November 28th, 1846. It was written after I had been twenty-eight days at work in my professorship, and it is as follows:—"Mr. Faraday in "the 11th series of his 'Experimental Researches on Electri-"city' has set forth a theory of electrostatical induction "which suggests the idea that there may be a problem in the "theory of elastic solids corresponding to every problem con-"nected with the distribution of electricity on conductors or "with the forces of attraction and repulsion exercised by "electrified bodies. The clue to a similar representation of "magnetic and galvanic forces is afforded by Mr. Faraday's "recent discovery of the affection with reference to polarised "light, of transparent solids subjected to magnetic or electro-"magnetic forces. I have thus been led to find three distinct "particular solutions of the equations of equilibrium of an "elastic solid, of which one expresses a state of distortion, such "that the absolute displacement of a particle in any part of the "solid represents the resultant attraction at this point pro-"duced by an electrified body. Another gives a state of the "solid in which each element has a certain resultant angular "displacement, representing in magnitude and direction the "force at this point produced by a magnetic body; and the "third represents in a similar manner the forces produced by "any portion of a galvanic wire; the directions of the force in "the latter cases being given by the axes of the resultant "rotations impressed upon the elements of the solid." Then come the mathematics, in three pages, and then comes the last sentence. "I should exceed my present limits were I to enter into "a special examination of the states of a solid body represent-"ing various problems in electricity, magnetism, and galvanism, "which must, therefore, be reserved for a future Paper." As to this last sentence, I can say now, what I said forty-two years ago, "*must be reserved for a future Paper!*" (applause). I may add that I have been considering the subject for forty-two years—night and day for forty-two years. I do not mean all of every day, and all of every night—I do not mean some of each day and some of each night. But the subject has been on my mind all these years. I have been trying, many days and many nights, to find an explanation, but have not found it.

Let there be an elastic solid body of exceedingly small density, and let there be a tubular portion of it porous, but with the same aggregate rigidity as that of the continuous elastic matter around it. Let the pores be filled with a dense viscous fluid, and let this fluid be forced, by aid of a piston or otherwise, to move through the tube. The pull of the fluid upon the porous solid will produce static rotational displacement exactly pro-

* Revised by Sir William Thomson.

Digitized by Google

portional to the continued rotatory motion which we had in in the case of the viscous fluid. Some of the most interesting practical problems of electro-magnetic induction can be dynamically realised, as it were, in model, by following out this idea; in fact, if we had nothing but electricity and ether, the thing would be done. If it were not for the gross ponderable matter that we are forced to consider, I should be perfectly satisfied with the problem of electro-magnetic induction, by taking the electricity as a viscous fluid, and ether an elastic solid, porous in some places, and continuous or non-porous elsewhere (applause.)

Now, if you will pardon me, though it is very late for introducing another topic on which to speak, I shall confine myself to one, and that is magnetism (applause.) I must return to the rotational case. Imagine this (Fig. 2 or Fig. 3) to be the section of an ordinary helix or solenoid with a solid copper core. Imagine a continuous electric current (Fig. 2) or an alternating electric current of electricity sent (Fig. 3) through it. Whatever the current of electricity may be, I believe *this* is a reality, *it does pull the ether round* within the solenoid. I do not think this is a dream of electro-magnetic theory—I believe it to be a reality. Whatever ether is we move through it—the earth moves through it. Astronomers and opticians do not cry out and make their lives miserable because of the aberration of light. Fresnel and Prof. Stokes have done all that man, up to the 9th of January, 1889, has been able to do to explain the dynamics of the aberration of light. It may be not beyond man's range to complete the solution—how the earth can tear through this elastic solid ether and yet the waves of light be propagated through it as they are. The aberration of light is still an absolute mystery.

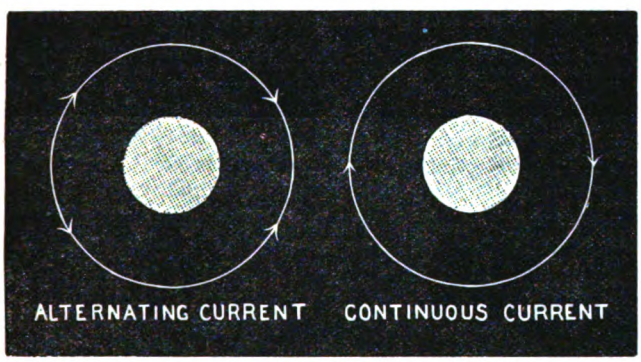

FIG. 3. FIG. 2.

Yet people who deal with optics and astronomy are not expected to be miserable for life because they have that difficulty ever before them. Well, are we to be absolutely unhappy because, while we see a mobile wire caused, in virtue of an electric current through it to move by electro-magnetic force, we cannot see any possibility of explaining how a medium capable of the "magnetic stress" can allow it to move? After all, great as the mystery there is, there is a mystery greater than that. The act of free will with reference to the laws of matter is a greater mystery than anything that has ever been suggested or imagined in the dynamics of ether, and electro-magnetism, and light (applause). Somehow or other, however it is, the ether is pulled round, the ether does get a turning motion in the interior of a solenoid; somehow or other it does give a turning motion to ether within our supposed copper core; and somehow or other there is a motion following these very laws we have been speaking of, and illustrated by the viscous fluid analogy.

But now for the iron. And now, instead of an alternating current through the helix, take a constant current through it. What can it do? One thing or the other it does: either a constant current through this helix drags the ether round and round inside, or it drags it round to a certain angle proportionate to the strength of the electric current, and brings it to static equilibrium so turned. It does either one or other of those things. Now, how on earth can iron differ, in the principle of the interfacial law, from copper? Our interfacial law depending on equal viscosities is quite clear, but when you introduce iron you introduce an interfacial difference depending on rotation, without anything that could possibly be a cause of any viscous action, or a cause of any elastic action. Elastic action (unless of compression or rarefaction, and these are not of our present subject) requires distortion. You have no elasticity of an incompressible elastic solid without distortion. Now if, by applying a tangential force all round the space within a cylinder, you keep turning the circumference, you will keep turning the contents. Ultimately the whole fluid within will go round with the same angular velocity as the circumference of the viscous fluid within it. Thus, our viscous fluid analogue works out perfectly well for the magnetic force within a solenoid having any non-magnetic material within it, and illustrates the fact that it is the same for conducting and non-conducting matter. But with iron the case is something quite different. Our viscous fluid analogue is called on to give us a greater permanent angular velocity, or a greater static rotational displacement, in the space occuped by iron in the magnetic analogue, than in this surrounding space! Thus, the primary phenomenon of the magnetisation of a bar of iron within a helix absolutely leaves us behind, cuts the ground from under us, both as to our viscous fluid analogy and our elastic solid analogy. If it is to be a fluid going round and round, we must have an action between the portions of fluid on the two sides of the interface, depending not on distortion but on rotation. Or if we take our elastic solid analogue, we must have static equilibrium of the elastic cylinder with the inner part turned through a greater angle than the rotational part of the displacement of the surrounding matter. An irrotational circular displacement subtracted from this procures fulfilment of the *no slip* condition at the interface. The distortion due to this irrotational displacement gives rise to a torque, tending to turn the matter within the interface! Hence, we must have an arrangement of matter in which a constant torque produces a constant angular displacement in a body, and does not produce continued rotation. The only thing that can do that is an inherent rotation existing in the molecules of matter. This seems the only thing that can do it, and this *can* do it certainly. But consider this, that the gyrostat shows us the thing done, and I will just conclude, if you will allow me, by a simple gyrostatic experiment—a very well-known old gyrostatic experiment—and I want to accentuate the application of it.

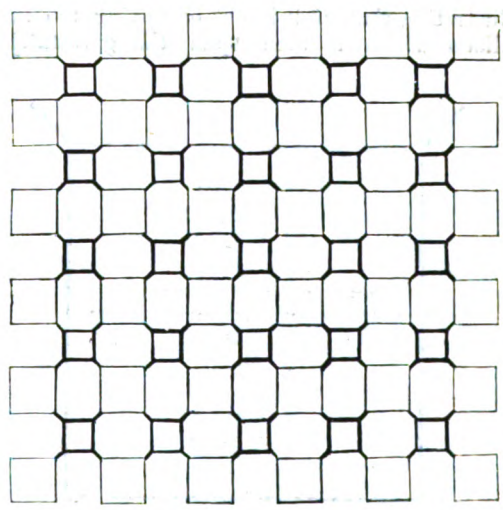

FIG. 4.

I am going to show by this illustration, with reference to the idea of a medium, a medium which has the properties of an incompressible fluid, and no rigidity except what is given to it gyrostatically. Here is, so to speak, a molecular skeleton that can give us such a fluid, a set of rigid squares with their neighbouring corners joined by endless flexible inextensible threads, running frictionlessly through holes in the corners, or round pulleys mounted in the corners (Fig. 4.) Here is a model, thus constructed: 36 rigid squares and 25 endless cord segments connecting the corners in this pattern, forming a kind of web. Now, if we take an ordinary cloth web, and pull it in different directions: in the direction

Digitized by Google

of the warp and the direction of the woof, you cannot stretch it; but at 45 degrees from the warp and woof you can stretch it very freely. We all understand that. You know how the surgeons take advantage of it in their diagonally-cut bandages. Now here is a web which is equally easily stretchable in all directions, and yet which is of constant area—a constant area for infinitesimal displacements, not a constant area for very great displacements. The circumference of each rigid and of each flexible square is given. Well, now, if you infinitesimally alter the square into a not-square rectangle, or into a rhombus, the area remains sensibly unchanged. The first change of the area is a diminution in whatever direction you stretch it, but that is proportional to the square of the strain, so that you may say, in language of infinitesimals, the area is unchanged. The constancy of the periphery, then, of each of these figures gives rise to and entails the condition of an approximate constancy of the area. Here, then, we have in this skeleton, a two-dimensional working model of a medium which is unchangeable in area, but is freely extensible in any direction, provided you allow it to shrink proportionately in the perpendicular direction. Well, now, let us put a gyrostat into each of those squares (Fig. 5), and you have all that is wanted to fulfil the strange, almost inconceivable, condition for a dynamical model of electro-magnetic induction in iron which I have put before you. I will just make an experiment illustrating that, if it is not occupying too much time. [Sir William Thomson then spun the gyrostat.] I turn

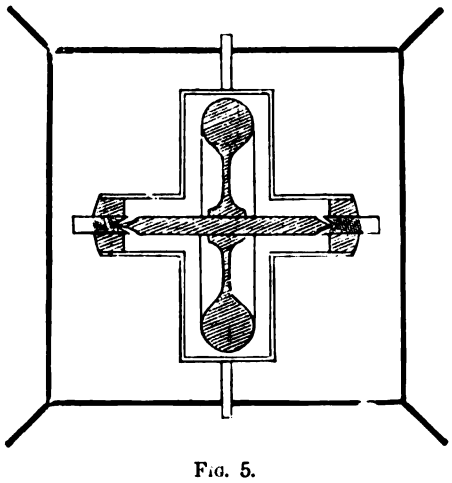

Fig. 5.

azimuthally the square frame by which I hold it; first in one direction, and the red end of the bearing of the axle of the fly-wheel turns up; I turn the other way, and up comes the blue end. The gyrostat is mounted in a square frame, as you see, which I hold in my hand. The rigid case bearing the axle of the fly-wheel is, as you see, free to turn round the axis of these trunnions, mounted horizontally on bearings in opposite sides of the square frame which I hold in my hand. The axis of these trunnions is perpendicular to the axis of the fly-wheel. I shall walk round and round to right, to keep the red side up; I walk round to the left, and it keeps the blue side up (applause). It is rather a curious thing. There are three little objects on a tray, as it were. Imagine this to be a butler's tray, with wine-glasses on it represented by these India-rubber corks. As long as I turn ever so little to my left all goes well; if I go straight forward, it is doubtful; but if I turn by an infinitesimal angle to my right, over it goes and everything falls off it (applause).

Look, now, at the gyrostat resting in this position on its trunnions, the axes of the trunnions and of the fly wheel being both at present horizontal. The outer square frame seems immovable in azimuth. When I apply a couple tending to move it in azimuth it does not move. It does not move in azimuth till the gyrostat turns round its trunnion-axis and brings its fly-wheel axis to be perpendicular to the plane in which I am trying to turn the square frame. And I must apply a couple whose time-integral is equal to double the moment of momentum of the fly-wheel before I can get the gyrostat from the position with the blue end up to the position with the red end up. Before I succeed in turning the square frame even a degree in azimuth I must have applied a torque whose time-integral is equal to twice the moment of the momentum of the fly-wheel.

This closed brass case, with a rapidly-rotating fly-wheel mounted on bearings inside it, is called a gyrostat, because in virtue of rotation it stands, however you place it, with any of its edges resting on a hard, smooth table. You see, place it as I will, it cannot fall. If I place it with its centre of gravity above the supporting point, it stands at rest. With its centre of gravity *not* vertically over the bearing point, it goes round in azimuth, *but it does not fall.*

Now, imagine mounted in each one of the rigid squares of this web a gyrostat exactly as this one is in the square frame which I hold in my hand. If the fly-wheel speed be great enough, each of those rigid squares is practically immovable in azimuth. I do not say it is immovable, but I say you may make it practically immovable by making the velocity of the fly-wheel sufficiently great.

Thus we have a skeleton model of a special elastic solid with a structure essentially involving a gyrostatic contribution to rigidity. Now, do not imagine that a structure of this kind, gross as it is, is necessarily uninstructive. Look at the structures of living things; think of all we have to explain in electricity and magnetism; and allow, at least, that there must be some kind of structure in the ultimate molecules of conductors, non-conductors, magnetic bodies, and non-magnetic bodies, by which their wonderful properties now known to us but not explained are to be explained. We cannot suppose all dead matter to be without form and void, and without any structure; its molecules must have some shape; they must have some relation to one another.

So that I do not admit that it is merely playing at theory, but it is helping our minds to think of possibilities, if by a model, however rough and unpractical, we show that a structure can be produced which is an incompressible frictionless liquid when no gyrostatic arrangement is in it, and which acquires a peculiar rotational elasticity or rigidity, as the effect of introducing the gyrostats into these squares. Imagine a corresponding model in three dimensions, with rigid cubes instead of the rigid squares which you see in the model before you. Instead of the endless flexible cords which you see, you may imagine elastic threads stretched between neighbouring corners of the cubes. In each cube mount three gyrostats, with their trunnion axes perpendicular to the three pairs of its faces. The gyrostatic domination thus provided causes the cubes to be practically immovable in rotation, but leaves them perfectly free to take translatory motion. There you have a body, then, that you could not distinguish from an ordinary elastic solid in respect to any irrotational distortion, or in respect to translational motion of the whole; but which if you try to turn it will not absolutely resist, but will only admit of turning by stretchings of the connecting elastic bands. It will not be immovable in respect of the turning, but it will be balanced by a constant couple with a constant degree of rotatory displacement. Thus, upon this solid the effect of a constant couple is not to produce continued rotation, but to produce and balance a constant displacement, and that balance might last for any time, however long, if the rotational moment of momentum of the fly-wheels is but great enough.

Now, lastly, I should just explain briefly that the rotational contribution to rigidity of ether in iron must be enormously less than in copper or in air. The total effective rigidity of the ether due to elastic action and gyrostatic effect in all non-magnetic bodies is the same. In iron there is less gyrostatic contribution, with equal elastic contribution, to the total rigidity. These conditions fulfil exactly what we want for the relation of ether between air and iron inside the helix of an electro-magnet. But alas! we are only led on to inscrutable difficulties. How much does our elastic solid go towards the explanation when in the very fundamental fact of the mutual motions by which electro-magnetic forces are made manifest to us, we have a force as of a strained solid between the bodies (magnets or wires) whose motions revealed to Œrsted and Ampère the existence of electro-magnetic force? Why is it

Digitized by Google

that those strains do not simply balance themselves in the solid? How can there be a solid capable of giving rise to that wonderful condition which we have in the air between the poles of an electro-magnet; for instance—such that a piece of copper will fall down through it at the rate of, perhaps, a quarter of a centimetre per second? Look on the subject as engineers, and think of the "strength of materials" wanted for ether in air, with the molecules of the air itself tearing through it in all directions at speeds averaging 500 metres per second, or more or less according to temperature. Think of the forces, amounting to 110 kilogrammes weight per square centimetre, with which two bars of iron magnetised to 1,700 C.-G.-S., with faces separated by a thin space of air, and with Ewing's 46,000 C.-G.-S. of magnetic force in the air around the bars, are urged towards one another. How can it be that these prodigious forces are developed in ether an elastic solid, and yet ponderable bodies be perfectly free to move through that solid? Now, I simply say all that has been done to think out this subject merely gives us a dynamical theory on one part of it. I have absolutely—not ignored, because I have spoken of it two or three times—but I have left out in the cold the electrostatic part, the thing we knew first. Our first love was electro-statics. That is absolutely left out in the cold. We do not touch it; we do not get near to explaining the mutual force between two electrified bodies in any of these illustrations or attempted explanations. We do not even get near the mutual attraction between the iron of an electromagnet, or the steel of a permanent magnet, and its armature or keeper; we do not get near to explaining the possibility of the motions of the bodies that demonstrate the forces. We only try to explain for a quiescent system of conductors and insulators, the variable distributions of electric currents which from mathematical theory and experimental observation we know to exist.

And here, I am afraid I must end by saying that the difficulties are so great in the way of forming anything like a comprehensive theory that we cannot even imagine a finger-post pointing to a way that can lead us towards the explanation. That is not putting it too strongly. I only say we cannot now imagine it. But this time next year; this time ten years; this time one hundred years, probably, it will be just as easy as we think it is to understand that glass of water, which seems now so plain and simple. I cannot doubt but that these things, which now seem to us so mysterious, will be no mysteries at all; that the scales will fall from our eyes; that we shall learn to look on things in a different way; when that which is now a difficulty will be the only common-sense and intelligible way of looking at the subject. I ask you to pardon me for leading you up to so impotent a conclusion as that we really know nothing below the surface of this grand subject, which constitutes the province of the Institution of Electrical Engineers (loud applause.)

Appendix.

Alternate Currents Through a Straight Conductor of Round or Rod of Non-Magnetic Material:—

Let σ denote the specific resistance in square centimetres per second (or the "specific resistance C.-G.-S.").
a ,, the radius of the wire.
R (S) ,, the value of $\sigma\, l \div \pi\, a^2$ [or the resistance (in centimetres per second) of any length l of the wire, with steady current through it].
R (N) ,, the effective ohmic resistance of the same length, l, with alternate current of N periods per second through it.
c (N) ,, the current-density at distance r from the axis, and at time t.
C (N) ,, the current density in the axis at time t.

We have $c\,(N) = C\,(N)\,(\text{ber}\, q \cos\theta - \text{bei}\, q \sin\theta)$

where q denotes $\left(2\pi\sqrt{\frac{2N}{\sigma}}\right) r$

,, θ ,, $(2\pi N)\, t$,

,, ber and bei denote two functions defined as follows:—

$$\text{ber}\, q = 1 - \frac{q^4}{2^2\,4^2} + \frac{q^8}{2^2\,4^2\,6^2\,8^2} - \&c.$$

$$\text{bei}\, q = \frac{q^2}{2^2} - \frac{q^6}{2^2\,4^2\,6^2} + \&c.$$

And if p denote the value of q with $r = a$, we have

$$\frac{R\,(N)}{R\,(S)} = \tfrac{1}{2}\, p\, \frac{\text{ber}\, p\ \text{bei}'\, p - \text{bei}\, p\ \text{ber}'\, p}{(\text{ber}'\, p)^2 + (\text{bei}'\, p)^2},$$

where the accents denote differential coefficients.

The following Table of Numerical Results has been calculated for me by Mr. Magnus Maclean, official assistant to the Professor of Natural Philosophy in the University of Glasgow.

For copper we have $\sigma = 1{,}610$ square centimetres per second. Hence, with $N = 80$ we find

$$q = 1{\cdot}98\, r \doteq 2\, r.$$

Thus, in respect to the ohmic resistance of the whole wire we may for copper take the column headed q as the diameter of the wire, and in respect to the distribution of the current through the wire (expressed by the ber bei formula above) we may take q the diameter of the cylindric shell in which the current density is to be calculated.

After the delivery of the Address,

GENERAL WEBBER moved "That the cordial vote of thanks of the Institution of Electrical Engineers be accorded to Mr. Edward Graves for the admirable manner in which he has discharged the duties of President of the Society of Telegraph-Engineers and Electricians during the past year." They expressed their thanks to Mr. Graves for the splendid way in which he had filled the President's chair. He had long ago distinguished

himself as the chief engineer of the Post Office, and during the past year he had endeared himself to them all by the way in which he had led them on every occasion when they had met together (applause).

Mr. C. E. SPAGNOLETTI most heartily, and with very great pleasure, seconded the vote of thanks. He had had the pleasure of knowing and working with Mr. Graves for very many years, and therefore could speak from personal experience to his excellent business qualifications, and the very ready and the very courteous way in which he dealt with all matters referred to him.

The PRESIDENT then put the motion, which was carried by acclamation.

Mr. EDWARD GRAVES said that when they did him the honour of electing him to occupy the chair which he had so recently vacated, he told them that it was a case of the wrong man in the wrong place, and he had not at all altered that opinion—in fact, if he did the address to which he had listened to-night would have corrected the error. But he had told them also that he would do his best; he had striven to do so. They had had many meetings during the year—many meetings of the Society, many meetings of the Council, many meetings of committees, and especially extraneous matters connected with the Lord Mayor's Committee and the Paris Exhibition. He had attended them all (applause), and now at the end he felt himself an official chief mourner at the deceased Society of Telegraph-Engineers, and he resigned to Sir William Thomson the much-pleasanter task of acting as god-father to the Institution of Electrical Engineers that took its place (loud applause).

Prof. GEORGE FORBES said that he had an extremely pleasing duty to perform in rising at the end of the evening to propose a hearty vote of thanks to their President for the admirable, instructive, and highly interesting address which he had given them, and to ask his permission to let the address be printed in the *Journal* of the Institution (applause). He thought everyone would agree with him when he said that they had that evening had one of those treats which it rarely came to them to enjoy—to hear the exposition from a man of Sir William Thomson's experience and position unfolding to them the result of the labours of his life, putting before them not only his personal recollections in connection with the advance of the science in which they were all so much interested, and in recollection of others who had worked with him, but also giving, as the result of this, advice to the members of the profession, young men and others, as to what subjects to pursue and so forth. In the advancement and development of their science Sir William Thomson had been so intimately connected that all of them felt they were being more closely brought in contact with the past history of their science when it was dwelt upon by him in such an address as he had just given to them; but he thought everyone would agree that what they had to thank him for mainly was the manner in which he had inspired them with some of the enthusiasm which he himself possessed in investigating the deeper problems of electrical science, and the interest which he had made everyone of them feel in trying to understand those brilliant analogies between the physical phenomena which were tolerably comprehensible and electrical phenomena which were rather obscure to them. He believed that he was the only member present who had the felicity to attend the three weeks' course of lectures which Sir William Thomson delivered at Baltimore on the undulatory theory of light, and he could give them some conception of what the feeling of all those who were fortunate enough to attend those lectures was when he said that for three weeks they had an uninterrupted exposition and a similar mode of treating the subject as they had had that evening; and it was a thing so rare that he felt everyone here would appreciate the treat which they had had in listening to the address that evening. Among the audience there were some very young members who had but little knowledge of mathematics, and there were also present among them the greatest mathematicians in the country, and yet he ventured to say that there was not one in the long range of abilities included by the audience who had not learned a great deal and had a great deal of new light thrown upon the subject in the course of that evening (applause); and he was sure that those who had not hitherto appreciated the benefits of mathematical investigation into the theory of such phenomena would be able to see from this address the way in which such a man could, by trying to get deep into the sources of things, be able eventually to apply such knowledge to practical phenomena. He remembered very well in 1874, just after the appearance of Clark-Maxwell's book, Prof. Tait, who took perhaps a too sanguine view of the work, considered that the book settled the whole question as to what electricity was—explained the whole thing. Prof. Tait said that some twenty-five years ago, he thought it was, Sir William Thomson had said to him, "if you will tell me what electricity is, I will tell you everything else," and Prof. Tait said, "Clerk-Maxwell had given us that information, and we must now apply to Thomson for the rest." All that evening they had been listening to Sir William Thomson in his attempts to explain, so far as it was possible at present, what electricity was, and what everything else was, too (applause). He felt quite sure that the vote of thanks which he was proposing would be most heartily agreed to, and that everyone in that room felt, as he did, that they had been listening to an address of a quality which it was almost impossible that they could expect ever to listen to again. They must, however, also thank Sir William Thomson for having come the long journey from Glasgow specially to give them the address, and to have taken the trouble to have been travelling all night for their edification. But it was not surprising that he should take this labour upon himself, when in the hour that he had been delivering to them an address he had been trying to compress the subject which he had been working out almost continually night and day for forty-two years. He begged to propose the motion which he had already read out (loud applause).

Prof. AYRTON said it had fallen to his good fortune—for he deemed it to be a good fortune—to be asked to second this vote of thanks, which he was sure they would all accord with the greatest enthusiasm to their new President. Within the last few months they had had the inestimable privilege of hearing their new President and seeing him in that room in two totally different capacities. A few months ago it was as an electrical engineer that he showed and described to them his most beautiful measuring instruments. To-night it was in a totally different capacity—as a theoretical electrician—that he had charmed them for such a long and interesting time, and it was the marvellous power that he possessed of combining theory with practice that had enabled him to accomplish the work that he had done, and which they all hoped he would live for a long time to continue carrying on (loud applause). They had in this country many engineers; they had also many competent mathematicians, but he ventured to think they had only one who could combine in the marvellous way they knew he had combined theory and practice—in fact, he might shortly say they had but one Thomson (hear, hear). On the previous occasion, when as an electrical engineer he was addressing them, he pointed out how important it was to study theory; to-night, as an electrician, he commenced with the diffidence which had marked all his work by telling them that, if they only became engineers, electricity they could grasp in a few months. He was sure that this thought would be a consolation to all engineers there to sleep on that night, that, if they only came into this room well armed with engineering knowledge, all this purely electrical science they would be able to grasp in a few months. That was a consolation, and he would be very sorry to remove that consolation from them; but at the same time he could not help feeling that this previous knowledge of electricity, if it were sufficiently complete to satisfy Sir William, would be something so vast and so comprehensive in its character as to appal the ordinary practical man. They all knew what a deep debt of gratitude was owed by electrical engineers, and he might say by the whole world, to that wonderful mathematical investigation that their President had touched upon so lightly—that investigation which made submarine telegraphy commercially possible. How Sir Wm. Thomson's pianoforte wire had sounded the deep sea—he meant the ocean, not the musical note (laughter)—was quite familiar to them. How his compass had guided ships to their journey's end was well-known to all the world. He dared say that on some occasions ships had started from a port armed with Sir William's compass on voyages of exploration, not, perhaps, quite knowing where they were going, or what they would find. And that night he had supplied them with another compass—a mental compass—and started them all on a voyage of exploration; and because he could not tell them what was the country that they would arrive at—it might be fifty or one hundred years hence—it did not make that mental compass that he had provided them with the less valuable, or diminish their unbounded feeling of gratitude for its gift (applause).

The motion was put and carried by acclamation,

Sir WILLIAM THOMSON, in reply, said: I thank you all very warmly for the kind manner in which you have received the motion which has been put before you. I thank the mover and seconder for the too kind appreciation which they have shown of my imperfect efforts to speak to you in proper terms this evening. I feel that your electing me to be President of the Institution of Electrical Engineers is really to myself a very great personal kindness, because I believe it was understood that, living as I do at so great a distance, I should not be able to do my duty properly as President, and to be here at all the meetings as I would like to be, or at the greater proportion of the meetings as I certainly ought to be, but only at a comparatively small number. I live four hundred miles away, and, as you know, have incessant occupation at that distance in Glasgow, so that it is practically not possible for me to be here at many of the meetings. I must ask you, therefore, kindly to excuse my inability to do myself the pleasure of being with you continuously, or even frequently, and I must trust to the kind consideration of the Vice-Presidents to take the place that I ought to occupy in the presidential chair. I hope to be present at all the meetings of the Society after the end of our Glasgow University session. If possible, I shall be at some before that time, but I am afraid that if at any it must be at but a very few; and I must ask you to kindly excuse me, and to know that it is simply the necessity of the case. It was necessary for me in fact to let it be known before you did me the honour of electing me, that this would be my case with reference to the important duties of the president of this institution. I may say that as regards the management of the business of the institution, I think none of us need feel any concern at all when we know that it is in the hands of our excellent secretary, Mr. Webb (applause.) He is always alive to the Society's interests, always attentive in carrying out the objects of the institution, and with the very great ability which he has shown we may feel that the management is in excellent hands. Then, with the Council here, in whom you have all such perfect confidence, I think you will not feel that the Society loses anything whatever in my absence. I thought it right that I should make my apology at present, as you have been so very kind to me this evening (applause.)

The Utilisation of Telephone Systems for purposes of Clock Regulation.—An attempt will shortly be made by the electricians of the Berlin Telephone Company to use their telephone wires for transmitting regulating currents to the clocks of the subscribers. Once a day about 5 a.m. all the subscribers' wires will be automatically connected to a central clock, and the time currents will be transmitted; the wires will then be automatically disconnected, and the usual service resumed.

THE WEST BROMPTON STATION OF THE HOUSE-TO-HOUSE COMPANY.

The West Brompton station of the House-to-House Electric Light Supply Company has been designed and erected by the engineer of the company, Mr. William Lowrie, on the lines of the system of electric distribution worked out by him at Eastbourne. With the set of offices, workshops, testing rooms, engineers' and drawing offices, the station is one of the most complete that has yet been erected in this country. At present it contains three complete sets of engines and dynamo plant, each set capable of supplying 4,000 50-watt incandescent lamps, and the completed station will have a capacity of about 48,000 lamps. The engines are of the horizontal type, and made by Fowler, of Leeds; the boilers by the Babcock and Wilcox Company; and the dynamos, of a special type recently designed by Lowrie and Parker, by Elwell-Parker and Company.

The situation is admirably adapted for a central electric lighting station, the plot of land, which is 470ft. long by 60ft. wide, being bounded on one of its sides by the Metropolitan District Railway, and on two of its sides by the London and Westminster Cemetery. The site is just within the boundary of the parish of St. Mary Abbotts, Kensington, and application has been made to the Board of Trade for a Provisional Order under the Electric Lighting Act to light this parish. Pending the granting of this Provisional Order, permits have been given to the company by owners of private property in the vicinity to lay mains underground, and in accordance with these permits the mains of the company are already laid throughout a considerable area.

The frontage in Richmond Road is taken up by the offices, consisting of public hall, clerks' office, secretary's office, board room, engineers' and drawing offices, and show rooms. The piece of land behind the offices has been utilised for stores, stables, cart-shed, yard, forge, meter, testing room, and engineers' shops fitted for doing all necessary repairs, or work required on installations and roads, ash store, and coal store, engine and dynamo room. The switch and regulating room, the testing room, stores, and office for the engineer in charge, are situated in the centre of the station; the latter being upstairs, and having windows on each side, has a full view of the works in both directions. Starting from these buildings, on the one side are the boilers, and on the other side the engines and dynamos.

The Dynamo Machines.—The alternate-current dynamos, one of which is illustrated in Fig. 1, are of a novel type. Running at 380 revolutions per minute the machine has an output of 100,000 watts. The mean speed at which the armature conductor is passed by the field-magnets is about 6,000 feet per minute, and the number of alternations 5,000 complete phases per minute; the E.M.F. is 2,000 volts. The armature, which is stationary, is built up on an iron core of large section composed of charcoal iron sheets thoroughly insulated from each other, arranged longitudingly and in the same plane with the magnetic fields; the conductor at full load carries 2,000 amperes per square inch of section.

The armature coils are formed of narrow tape, each wound in a plane (or slightly curved to suit the radius) upon a piece of insulating material of the same thickness as the width of the tape, and rounded at the ends. The coils are thus of a flat link shape, the edges of the tape windings being exposed upon the flat surfaces of the coils, and therefore well able to resist deflection. These coils are placed close together upon the cylindrical inner surface of the armature ring, so that the axis of each coil is radial to the ring. They are secured by rebated strips of wood, screwed to the cheeks, and extended over the ends of the coils, outside the line of travel of the magnets. By this mode of construction the whole of the conductor (except a small portion at the ends of the coils parallel with the line of travel of the field) is placed under exactly the same inductive influence, and at the same distance from the moving poles, and consequently in the best position for efficiency.

Another great advantage is that no special means are required to keep the conductors from sagging or lifting from their normal position, and thus the clearance space is reduced to a minimum. Furthermore, as the armature coils are simply secured to the face of the armature, they are easily removed

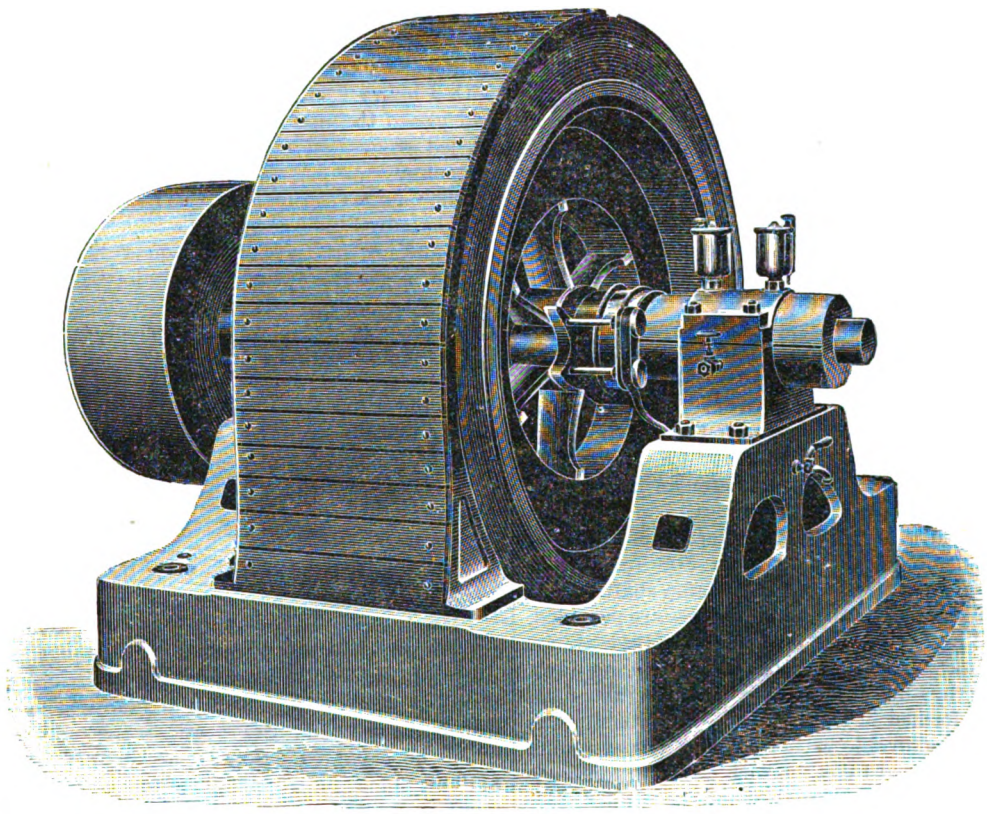

FIG. 1.—THE LOWRIE-PARKER DYNAMO. It will be noted that this machine is shown with a belt pulley, but the dynamos at the West Brompton Station have pulleys for rope gearing.

Digitized by Google

or replaced as required. The armature ring is parted upon the horizontal line, so that the upper half is removable for inspection or repairs. The frame for supporting the laminated iron armature core is cast separate, and securely bolted to planed facings.

The revolving field consists of a solid soft wrought-iron ring, with pole-pieces securely attached thereto, and is arranged so that the centrifugal force of the whole of the moving parts is taken by the ring. The energy absorbed by the field does not exceed 5 per cent. of maximum ontput. The base-plate is of box-pattern, and strongly ribbed and under flanged where it bears on the slide rails. The plummer blocks for the bearings are cast separate from the base-plate, and secured by bolts, and lugs, and wrought-iron wedge keys.

The bearings are two in number, 20 inches long; they are in halves jointed on the horizontal centre and fitted with loose brasses, top and bottom. These brasses are of hard phosphor bronze. The bottom brass is so arranged that it can be removed without lifting the shaft, and yet well secured sideways; each bearing is fitted with two combined syphon and sight-feed lubricators. Each end of the bearing is provided with oil catchers, consisting of a chamber all round the shaft, by which the oil passing from the bearings is caught when thrown from the oil throwers provided on the shaft, and conducted by a passage formed in the plummer block under the brass to a waste oil tank or receiver formed in the plummer block or the base plate; each tank is provided with a drain cock fixed in suitable position for drawing off the waste oil.

The shaft is of best mild steel, 6 inches in diameter, the side thrust being taken by collars, forged solid on the shaft at each side of one bearing only; double grooves are cut for throwing the oil into the collectors provided at each end of the main bearings. Mounted on this shaft is a hub of cast iron, attached to the ring on which the magnets are mounted in such a manner as to prevent any magnetic short-circuiting. The rings on the shaft for collecting the exciting current are insulated from the shaft and from each other by ebonite washers. The brushes and holders are supported from the base plate. The driving pulley is of cast iron, double web type, with turned grooves for seven 1½in. cotton ropes, diameter 40in. Fixed to the dynamo is also a pulley of suitable diameter for driving the exciter, turned with grooves for four ¾in. ropes.

The exciter is a 12-unit series-wound inverted machine by Elwell-Parker, with drum armature, run at 800 revolutions per minute, and driven by ropes from the dynamo shaft.

Efficient means for tightening the driving ropes are provided, consisting of two cast-iron rails of heavy section, fitted at one end of each with forcing screws; provided with holding-down bolts for the dynamo, the nuts of which are of rectangular form and sliding in grooves formed in the rails. The bolts being thus applied from above are removable without lifting the dynamo. The two rails are securely tied together with cast-iron distance pieces. Similar arrangements are supplied for the exciter.

The approximate weight of the dynamos is 10 tons, and of the exciter 1 ton.

All around the dynamos and exciters is a highly insulated platform of crossed floor boards set on joists, with bitumen between the two sets of boards and linoleum laid throughout. This platform is raised 6in. above the general floor line.

The Engines.—The machines are each driven by a horizontal coupled compound engine, specially designed and made to specification by Messrs. John Fowler and Co., Leeds, capable of indicating 200 horse-power on the brake at its most economical load; steam being cut off from the high-pressure cylinder before the piston has completed more than one-third of its stroke. The high-pressure cylinder has a diameter of 15 inches, and the low-pressure cylinder is 25 inches in diameter. The stroke is 30 inches, and the initial steam pressure 150 pounds per square inch. The speed is 88 revolutions per minute. Both cylinders are steam jacketed, and are fitted with separate liners. All the cocks on each cylinder are joined together by rods and levers, and brought, with handle, within easy reach of the man standing at the starting valve. Cylinder lubricators are fitted to both valve chests, and an extra sight-feed cylinder lubricator is fitted to high-pressure steam chest. The low-pressure cylinder is fitted at both ends with automatic relief valves; both valve chests are provided with a seven inch steam pressure gauge and cock. The steam feed is from above, and the exhaust is from the bottom side of the low-pressure cylinder. The pistons are of cast iron, with cast iron rings and Junk rings, and Pollet and Wigzell's springs behind the rings; the piston rods are of steel, separate from the cross heads, and secured to them by cotters. The connecting rods are made of best hammered scrap iron, polished and fitted with large adjustable brasses, marine type at crank ends; the gudgeon pin on cross head is forged scrap iron, with means for taking up wear; the length of the rods between centres is 2½ times the stroke of the engine.

The crank shaft is of best mild steel, 8in. diameter in the bearings and 12in. diameter where the key ways for the fly-wheel or pulley are cut. The crank disc at each end is of cast iron, and shrunk on to crank shaft and secured with a key. The crank pins are of steel, slightly conical to fit into the disc, keyed and pressed into place by hydraulic pressure, and riveted into position. The lubrication for each crank pin is effected through the centre of the crank pin and a pipe carrying a receiver revolving concentrically with the crank shaft, this being supplied with oil from a sight-feed lubricator, fixed to the base plate. A main bearing, 16in. in length, is cast in one piece with each base plate, and fitted with brasses of gunmetal arranged for top and side adjustment. Each engine is fitted with a heavy fly-wheel, 14ft. diameter, made in halves, planed and joined through the centre, turned on the edges, and with turned grooves on the face, for driving with seven ropes, 1½in. diameter.

The engines are fitted with Hartnell's governor, driven from the shaft by four cotton ropes, which acts directly on both the high and low pressure expansion valves, and gives a range of cut off in the high-pressure cylinder from 1 per cent. to 60 per cent. of the stroke. It governs the engine to within 2 per cent. A complete set of indicating gear is fitted to each cylinder. The approximate weight of engine is 24 tons.

[Owing to the pressure on our space we are compelled to defer a description of the remainder of the equipment until next week.]

(*To be continued.*)

REVIEWS.

Mechanical Drawing; A First Course. (Tracing.) By Geo. Halliday, Instructor at the City and Guilds Technical College, Finsbury. (E. and F. Spon, London and New York.)

Mr. Ruskin once horrified the drawing-masters by recommending the use of ruler and compass until the pupil has learnt to appreciate the niceties of straight lines and curves, when he may be safely trusted to draw them accurately without such aids. Instructors of mechanical drawing in many a college and institute may possibly be equally scandalised at the novel departure which Mr. Halliday, who occupies a similar position in the Finsbury Technical College, has struck out by the advocacy of a course of tracing exercises leading up to, instead of following, the art of mechanical drawing and design. Neither the Education Code nor South Kensington offers the slightest encouragement to science schools and colleges teaching this very A B C of mechanical drawing; and the result is that pupils very generally begin their course of instruction, so far as scientific drawing is concerned, at the wrong end. Mr. Halliday insists that the same method be adopted in the class room as prevails in every practical drawing office; and the book before us contains a series of progressive examples as a first course, with instructions for the pupils' guidance whether under a master or not. It is to be desired that Mr. Halliday's method and his vindication of it should be known to every science teacher in the kingdom.

THE HOOKHAM ELECTRICITY METER.

In describing the central lighting station at Leamington (*The Electrician*, August 17, 1888) we promised at a later date to describe in detail the very ingenious meter devised by Mr. Hookham, which has been in use at Leamington since January, 1888; this promise we now fulfil. The most striking peculiarity of this meter is to be found in the remarkably slow rate at which it can revolve without losing proportionality. It has, therefore, a wide range, one size measuring from ·4 to 20 amperes, and another from ·6 to 40 amperes. The loss of energy in this case is only about one-tenth per cent., but where a somewhat higher rate of loss of energy is not objected to—as, for instance, for station service—a range of as much as from 1 to 250 can be obtained.

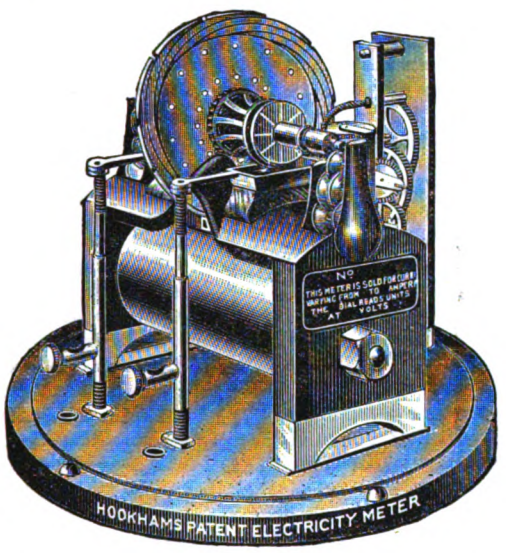

FIG. 1.

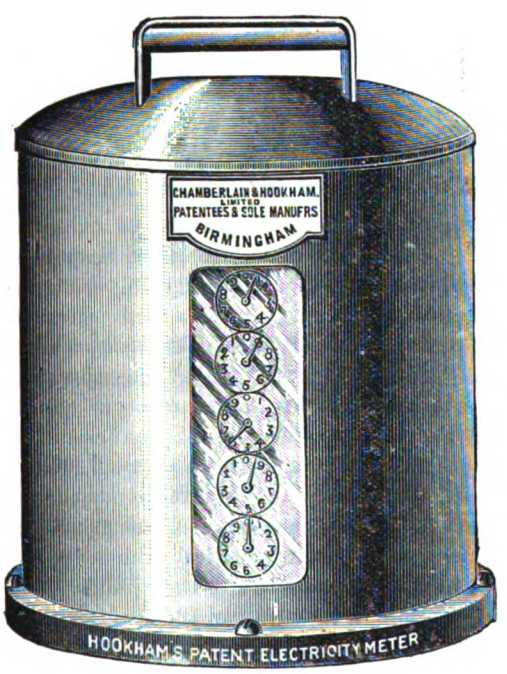

FIG. 2.

The meter consists essentially of an electro-motor doing work against Foucault currents, under conditions in which other retarding influences are negligible. When this is the case, and the armature carries the current to be measured, the field remaining constant, the speed of the armature will vary directly as the current. For the work done is proportional to the square of the speed; the brake-force varies as the speed; hence the speed will be proportional to the driving force, which, again, in a constant field is proportional to the current to be metered.

The engraving (Figs. 1 and 2) illustrates a meter for a thirty-light installation. The armature sections are built up on a copper disc, the connections passing spirally round the edge of the disc. The disc and armature rotate together between the poles of the magnet. These are of cast-iron, the magnet bars of tungsten steel being contained in a brass tube beneath. The reduced ends of the armature spindle roll on the uppermost wheels of anti-friction trains, and a commutator in which mercury contacts replace spring brushes, and which is practically frictionless, is an important part of the device. Iron is not used in the armature, so that magnetic drag does not enter as a disturbing cause. The motions of a worm-wheel driven by a screw-thread on the armature spindle are transmitted to the counter. At present the magnets are fitted with a short-circuiting bar, whose distance from the cast-iron arms of the magnet can be adjusted. The object of this arrangement is that if the field is found to fall off it can be reinforced by removing the bar to a greater distance. In practice this has proved to be a superfluous precaution, as, after many months' testing of a considerable number of meters, in no case is there the slightest indication of the field falling off. The cause of this constancy of field is no doubt to be found in the fact that the air-space resistance is extremely small, and the magnetic circuit consequently almost closed. A further advantage of this closed circuit is that it is impossible to tamper with the field by means of external magnetism, especially as the whole apparatus is enclosed in a stout iron case. This case is glazed at the part opposite the dials, and need not be removed, even at the quarterly visits of the meter inspector.

This meter is at present made for continuous currents only, but the principle would seem to be equally well adapted for alternating currents.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To night) FRIDAY, February 1st.

ROYAL INSTITUTION.

9 p.m. "The Life History of a Marine Food Fish." By Prof. W. C. MCINTOSH, M.D., F.R.S.

MONDAY, February 4th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

SOCIETY OF ENGINEERS.

7:30 p.m. First Ordinary Meeting for the year 1889, at the Town Hall, Westminster. Inaugural Address by the President, Mr. Jonathan R. Baillie.

TUESDAY, February 5th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture, "Before and After Darwin." By GEORGE JOHN ROMANES, M.A., F.R.S.

SOCIETY OF ARTS.

8 p.m. Applied Art Section, "Manufacture of Sevres Porcelain." By EDOUARD GARNIER.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Discussions on the Papers read at the last Meeting. Time permitting, a Paper will be read on "Some Canal, River and other Works in France, Belgium and Germany," by L. F. VERNON HARCOURT, M.A., M.I.C.E. At this Meeting the monthly ballot for members will take place.

ROYAL VICTORIA HALL.

8:30 p.m. Lecture, "Torpedoes." By Prof. A. W. REINOLD, M.A., F.R.S.

WEDNESDAY, February 6th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "The Status of the County Council." By G. L. GOMME, F.S.A.

THURSDAY, February 7th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture, "The Metamorphoses of Minerals." By PROF. J. W. JUDD, F.R.S.

FRIDAY, February 8th.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. "Flexible Wheel-Bases of Railway Rolling Stock." By G. D. TWINEBERROW. Stud.Inst.C.E.

ROYAL INSTITUTION.

9 p.m. Evening Discourse, "Electrostatic Measurement." By Sir WILLIAM THOMPSON, F.R.S.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714.

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—			
Within Postal Union	s. d. 6 6	s. d. 12 6	s. d. 24 0
„ Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1888, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 will BE READY NEXT WEEK

CONTENTS OF THE CURRENT NUMBER.

NOTES 357

SPECIAL NOTICE.

The last number of "THE ELECTRICIAN" contained a Steel Plate Portrait of Sir WILLIAM THOMSON, F.R.S., President of the Institution of Electrical Engineers.

A few copies of The Portrait, on large Paper, neatly framed in Brown or Black, will be supplied (carriage paid) for Four Shillings and Sixpence.

UNDERGROUND WIRES IN NEW YORK.

IT was inevitable that the question of overhead electrical wires would come up for discussion some time this year, and the remarkable activity of electric lighting business under the new Act has, no doubt, precipitated a fresh attempt at settlement. As reported in our last week's issue, a committee has been formed by the Board of Trade, in conjunction with the Institution of Electrical Engineers, to report upon the subject, and this committee will probably command as much confidence as any body of men that could have been selected. Moreover, their labours will be materially lightened by the fact that the evidence of the Parliamentary Committee taken three or four years ago, and the still more practical evidence from experience in the United States, are ready to their hands. The action of the Board of Trade in thus calling in the aid of expert advisers may be taken as an indication that it is not disposed to exercise the powers it already possesses in a hasty or high-handed fashion; and we may assume with confidence that the Institution of Electrical Engineers will not lend itself to recommendations which would unfairly hamper the industry with which it is so closely associated, and for the free development of which the public have evinced so much anxiety.

It may be assumed that while the committee is in existence opportunity will also be taken to consider the even more important question of underground wiring. In this connection the Report of the New York Board of Electrical Control, pub-

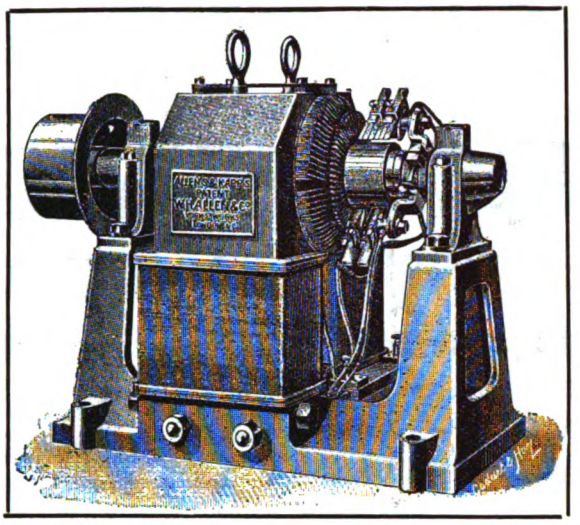
W. H. ALLEN & CO., York Street Works, Lambeth, S.E.

MAKERS AND PATENTEES OF THE

"KAPP DYNAMO."

The only Dynamo that has the following combined advantages: Perfect Ventilation, Positive Driving, No Wasteful Internal Currents, No Heating, Self-Regulation, Slow Speed, and Good Workmanship.



The most reliable for Arc or Incandescent Lighting, Electro-deposition of Metals, Charging Accumulators, and Transmission of Power.

Made direct acting with Allen's High-Speed Engine, for long and continuous runs and constant use, without break-down or repairs.

A LARGE NUMBER OF THESE MACHINES ARE AT WORK, GIVING EVERY SATISFACTION

"TELEGRAPH CONVENTION" CODES.

Now Ready, the ENGLISH, LATIN, FRENCH, GERMAN, DUTCH, ITALIAN, SPANISH and PORTUGUESE CODES

lished on the 21st of last month, will necessarily have considerable weight; and although the evils which are complained of in this country are not to be compared in magnitude with those which the New York Board has had to contend against, they are pretty much the same in kind. In New York the overhead wires have become not only a public nuisance, but a public danger; and although it is inconceivable that they could grow to a similar extent anywhere in this country, the English are a more fastidious people than the Americans; and we may be thankful, therefore, that the matter is being taken in hand with us at an early stage, so that no drastic and arbitrary remedies may be needed here, as they have been in New York. On this point the experience of the Empire City is a standing warning. Such has been the progress of electrical business there that the construction of underground conduits and subways, although pushed on rapidly by the Board of Control during the past two years, has not kept pace with the requirements of the wiring. The Board is constrained to admit its failure in this respect in the following terms:—"Notwithstanding the fact that there are 4,500 miles of underground conductors in the City of New York, and notwithstanding the removal of a considerable number of poles and wires during the past year, it is safe to say that there are to-day in the city of New York more overhead conductors than there were a year ago." Possibly the true explanation is to be found in the fact that the companies have not yet fully developed their systems in the several areas—a condition which, as we have often insisted upon, should be fulfilled before the mains can be judiciously placed underground in any permanent fashion.

With the election of a new Mayor pledged to support the Board some hopes are held out that its powers will this year be energetically enforced and greater progress made with the underground conduits. As to the powers, no one can complain of their inadequacy. After a ninety days' notice the Board can pull down the poles and wires of any refractory company refusing obedience. But in exercising these powers the Board has been hindered by two considerations besides the personal one already alluded to; namely, the want of funds to pay for the demolition, and the want of sufficient accommodation for the ever-increasing number of exposed wires. Provision on these heads it is expected will be made during the present mayoralty. The conduits, however, themselves have not always come up to the Board's own standard of efficiency, which does not appear to be excessively high. Not only are they open to the criticism of the offending companies, which was to be expected, but they are assailed by water and steam from other companies supplying those commodities, which had never been expected. As regards the water, the Board promises amendment by improvement in construction; and as to the hot steam, if the companies who generate it do not stop the leakage, they will be held responsible for the damage done to the wires. This is all very well by way of promise; but meanwhile, in the matter of performance, the electrical companies prefer to bear the ills they have already rather than fly to others they know not of. In plain words, bad as it confessedly is, the insulation of their overhead wires is under control, whereas the insulation underground is not. That this is the view taken by the electrical companies comes out clearly from an examination of the figures supplied in the Board's report. The lengths of trenches excavated and conduits already constructed are stated in feet—apparently to magnify the undertaking—whereas their capacity for accommodating wires is stated in miles. This is a little perplexing; but comparing the estimated accommodation offered with the actual amount used, we learn that for the telegraph and telephone services room can be found for 34,665 miles of wire. At present there appears to be only 4,250 miles of such wire occupying this vast space. For lighting and power service the "duct conduits" are estimated as sufficient for 600 miles of wire, whereas their actual occupants measure less than 9 miles. It ought to be mentioned here that the Edison Company have 192 miles of underground wire for lighting purposes placed in their own system of conduits. But on the whole it cannot be said that the electric lighting companies of New York have shown the desired readiness to remove their conductors from above-ground; and it still remains to be seen whether the Board of Electrical Control will be able to compel them to do so during the present year.

The Board is on safer ground in dealing with the telegraph and telephone wires. The local evidence it adduces in respect to their safety and efficiency when placed underground can hardly be gainsaid; and it is backed up by similar testimony from Boston and Chicago. But the Report is significantly reticent, or disappointingly obscure, as to the one point on which above all others we would have desired explicit information, namely, the feasibility of laying electric lighting wires on a large scale, and with various methods of working, in these excavated subways. At all events, the experiment has yet to be tried; and at present the New York lighting companies are not contented with the provision made for trying it. This being the case, the Board has wisely devoted a good deal of its Report to framing regulations for wires that remain overhead, and are likely to remain. Among these we may mention one which has at least the merit of being calculated to prevent the unnecessary multiplication of poles. In granting permission for their erection the Board stipulates that they may be used by any other company desiring to do so, and offering proper payment for their use. Of the electrical regulations framed by the Board, they are such as would suggest themselves to any competent committee who may take the matter in hand in this country. We feel sure also that any English committee will act in the spirit, if it does not adopt the language, of the New York Board's Report, where it is urged that as "electrical business is a development of civilisation in its highest form" any interference with that business should be for its "reasonable and proper regulation, not for its retardation or obstruction."

ELECTRIC METERS FOR CENTRAL STATIONS.

At the meeting of the Society of Arts, on Wednesday, the 23rd January, Mr. W. H. Preece, F.R.S., in the chair, Prof. George Forbes, F.R.S., read the following Paper:—

There is no department of electric engineering which has interested me and occupied my thought more than that of central station work and the distribution of electricity from these centres throughout a town for the production of light and motive power.

It was before this Society that I had the honour of classifying and developing the systems of distribution at the disposal of the electrical engineer.* The position in which we now find ourselves is that for extremely concentrated areas a direct supply with continuous-current dynamos, sometimes assisted by secondary batteries, and working on the three-wire system, is the most successful and the most remunerative. That is the result of experience, I think I may say, in all parts of the world. But for extensive areas the use of high-tension alternating currents in our mains, reduced in the houses by means of induction apparatus, is the most economical and flexible. This is the system which was first published and used by Gaulard and Gibbs. To take examples in the city of London. While we prefer the adoption of high-tension alternating currents by a company which is preparing to supply the whole of London with electric light, yet I felt that for the concentrated area bounded by Pall-mall, Green Park, Piccadilly and Haymarket, it was far best to recommend the low-tension three-wire system; and we may safely look forward to seeing that central station, though it is on the low-tension system, certainly one of the most satisfactory in the world from every point of view. This is owing

* Cantor Lectures, 1885.

Digitized by Google

to its concentrated area and the large consumption of light in the district.

It always seemed to me that the success of such central stations depends largely on the working out of details in the arrangements, details in the mechanical parts, details in the electrical parts, and I have seldom, if ever, visited any such stations without seeing new points of detail, and learning new facts about the causes which lead to success and failure.

In order that we may make as few mistakes as possible in our central station work, one must try to learn as much as possible from countries which have made a greater start than England. It was for this reason partially that I was led to visit the stations established on various systems in the United States, and lately I have done the same thing with respect to the most important of the central stations in Europe.

Both in Europe and America there is one maxim which I find is conclusively established as the result of practice—this is, that the best paying stations are those in which the electricity is charged for by meter, and not at so much per lamp per annum. Both these systems are in use, but companies who have used both give their unqualified and undivided testimony in favour of charging by meter.

I propose to deal with this important point of detail to-night, and to tell you something about the working of different types of meters in the United States as well as in Europe.

Now first let us settle the question what it is we want to measure. Both with gas and with electricity, if the company supplies burners or lamps, it would be most desirable to measure the light given off. But this plan is not likely to be adopted in England. In other countries it frequently happens that the electric lamps are supplied by the company which is supplying the electricity; but that has not been the case hitherto in England, and I think we may take it as pretty certain that that is not the plan which is going to be adopted. The private consumer in this country will generally supply the lamps as he does the burners for the utilisation of gas. Hence what we come to is that we want to measure the gas or the electricity consumed. We want to measure its light-giving power. To do this we must know the quantity consumed and its quality. With gas, the latter is impossible to measure in the meter. We can only measure the quantity of gas consumed. We cannot by means of the meter measure its pressure nor its purity, nor the quantity of air or sulphur combined or mixed with it. These points are left to inspectors to determine, who shall insist upon a standard being maintained.

With electricity it is different. When we have measured the quantity consumed, there is only one quality which can exist, and that is its pressure. If, then, our meters measure the quantity consumed, and inspectors keep watch to see that the pressure is always maintained constant, the consumer's interests are amply looked after.

Now it has been suggested that we really ought to measure not the quantity of electric current which is consumed, but the quantity of energy. Now the energy is the product of the quantity by the pressure, and could easily be measured if desired. There would be no object, however, in doing this. A deficiency of pressure is certainly undesirable, because the lamps burn less brightly, and the customer would be charged less if such a system were used, and so far the plan would be advantageous. But, on the other hand, an excess of pressure is equally objectionable, because it injures the lamps, and it would not be fair to charge the customer more for the quantity he uses under these conditions. Hence, the energy of the current is not what it would be fair to charge the consumer. The only fair way is to do as with gas, *i.e.*, to measure the quantity used and guarantee the quality, *i.e.*, the constancy of pressure. This should never vary more than 4 or 5 per cent. at the most. For perfect lighting a variation of 2 or 3 per cent. only can be allowed. I trust that in the immediate future, when we certainly expect to see an enormous development of central station lighting in this country, great precautions will be taken to see that the variations of pressure do not amount to a serious quantity. There is too much evidence, I fear, that sufficient attention is not always paid to this point, and I have myself seen in some central stations in this country a very large variation of pressure over the district which is being lighted. I hope that the fault will be thoroughly appreciated in the central stations which are being put down now, in order that we may have less ground for complaint against the electric light.

I intend to direct your attention to various kinds of meters which have been put into actual practice, but before doing so it will be well to point out some of the *desiderata* in a perfect electric meter. I will deal with these in order.

1. *Accuracy.*—The meter must be at least as accurate as an ordinary gas meter; in fact, that standard is rather low for modern requirements (hear, hear). The question of accuracy is twofold. First, the readings of the meter must be accordant with different strengths of current passing through the meter, and for all rates of supplying electricity within its range. These readings should be quite accordant; when we take 10 times as much current out of the meter, we ought to get exactly 10 times as large a reading in a given time. Secondly, the indications of different meters must be consistent. This latter point is largely one of manufacture, and in the construction of some meters it becomes a very important point to see that it is easy to manufacture the instruments in large quantities, and that the different instruments will be exactly similar and quite comparable in their effect.

2. *Range.*—It is desirable that the meter should be capable of working accurately over a large range of current strength. It would undoubtedly be desirable that the meters made for the largest currents which can be used on a circuit should also be capable of indicating correctly when only one lamp is in circuit. So far as I am aware, no electric meter has been invented fulfilling this requirement. It has often been proposed, with circuits of very many lamps, to have two meters—one for small currents and the other for large ones—and to switch in the latter automatically when the current exceeds a certain amount, and to switch it off again when the current falls below that amount. It is perfectly easy to devise electrical apparatus which shall act automatically and in this manner, but at the same time there is a serious objection to any such arrangement which involves an occasional use of a contact breaker, owing to the sparking and consequent deterioration of the contact. A far better plan, and that which is adopted, I believe, in most stations which employ meters, is to wire the houses in separate circuits of 20, 40, 60, or 100 lamps, according to the effective range of the meter adopted, using a separate meter for each of the circuits.

3. *Consumption of Energy.*—Energy must not be consumed by the meter to such an extent as to diminish injuriously the voltage supplied to the lamps. The loss of energy in any meter is likely to be extremely small, regarded simply as loss of energy—as cost of energy. That is a point about which there need be, I should think, no fear. But it is desirable to see that the meter has not sufficient resistance to reduce the voltage of the lamps when the full number of lamps is on. The wiring of a house generally diminishes the voltage at the maximum about 2 per cent., according to present practice in this country. A meter ought not to increase this loss by more than ½ per cent.

4. *Simplicity.*—The meter should be simple to construct, and not liable to get out of order. Extreme delicacy in moving parts is to be avoided when possible.

5. *Durability.*—It is essential that no parts of the apparatus are liable to wear out rapidly, because not only would there be an expense, but it would lead to irregular action of the meter.

6. *Attention.*—Other things being equal, that meter is the best which requires least attention. Any winding up of clockwork is objectionable, and the necessity of removing the meter or part of it from the consumer's premises should be avoided.

7. *Registration.*—The meter should register in a clear manner, so that the consumer can read it at any time and check its accuracy. A system of geared wheels with indexes and pointers, like a gas meter, is very convenient.

8. *Testing.*—A point of some practical value is that it should be an easy matter to test the meter, and that the operation should not occupy much time. We find a great diversity in different types of meter on this head. Some meters which are very slow in producing a single indication require many hours—it may be even a day or so—to test it for the small currents; and to test it over the whole range of the currents occupies many days with some meters.

9. *Cheating.*—With some meters the process of cheating is easier than with others. I speak chiefly of cheating on the part of the consumer (laughter). I notice that generally when I have been speaking about meters with people the other possible way of cheating is not considered of much importance (renewed laughter). The possibility of short-circuiting the meter is common to all, and can be obviated. Some meters can be retarded by placing a magnet near them, others by heating them locally, others by putting them out of level. This last can be prevented by securely fixing the meter to a wall or floor.

10. *Economy.*—Of course, it is very desirable that the meter should not be a very costly apparatus. It will not be practical if it entails a large rental, and so adds much to the quarterly bill.

11. *Freezing.*—A meter which contains a liquid which can freeze is objectionable in any but warm countries, since a lamp or other resistance must then be put inside it to keep it warm, and this is a constant source of waste of energy.

12. *Alternating and Continuous Currents.*—Some meters are only usable with continuous, others with alternating currents. A meter which reads with equal accuracy for both kinds has a double value. Many stations supply both classes of currents, and it is less inconvenient to deal with only one type of meter.

13. *Number of Alternations.*—Meters for alternating currents ought to indicate with equal accuracy, whatever be the alternations per second. Otherwise irregularities will occur, and also the other kind of cheating is likely to come in—that is to say, the supplier of

Digitized by Google

electricity can cheat by altering the number when under test, and also when at actual work.

14. *Contact-breaking.*—No contact-breaker of any electric circuit should be allowed in a meter, because such contacts deteriorate with use.

15. The meters should be so substantial that they can be sent by rail without accident. I have here grouped together the 15 principal points which have occurred to me, and I think to others, as the points which have to be considered in relation to electric meters. I have discussed many of these different points with manufacturers in different countries, and I think this list includes pretty well all that have either suggested themselves to me, or which other people have spoken of.

No one meter fulfils all these requirements. But all the meters which I am going to describe fulfil many of them, as they all have done good practical work on central stations. I am not going to make any invidious comparisons between the merits of different meters in what I say this evening. I have put before you the desiderata which are to be obtained, and I feel quite confident that the meters which I am going to describe are all very good meters; and I feel also sure that those meters which fulfil the conditions which I have enumerated most satisfactorily, so as best to meet the requirements of central station lighting, will be the most successful in the future, and will be used most generally. Everyone will see that that is the logical thing, and that it is much better to leave the comparison of the relative merits of different meters to the actual tests of experience, than to dilate on them, except in the most hypothetical sort of manner, at the present stage of electric lighting.

In all the meters which I have to describe the registration is effected either by moving mechanical parts or by electrolytic decomsition. In most of the mechanical meters a certain dynamical principle has been employed to guide the inventor to an accurate instrument for different strengths of current. I will now briefly explain the general idea of this principle, which has helped people very much. In the class of meters I allude to the electric current sets some mechanism in movement. Now we all know that generally the work done by a current in a given time varies as the square of the current. Thus the electrical force tending to drive the mechanism is proportional to the square of the current. Such mechanism would increase its speed indefinitely under the influence of such a force if there were no friction opposing the increase of speed. In the meters I allude to, the friction of the air or of a fluid is opposed to the driving force of the electric current. This resistance increases as the square of the velocity. The electric force goes on increasing the speed of the mechanism until the opposing friction equals the driving force of the electric current. But the friction varies as the square of the velocity, and the driving force varies as the square of the current. Hence, in all cases where the mechanism acquires uniform speed the square of the velocity is proportional to the square of the current; in other words, the velocity varies as the current. Now, the indications of such an instrument as shown by an index gives the number of revolutions of the mechanism in the period of testing, which means the velocity multiplied by the time, and this is proportional to the electric current multiplied by the time. Hence the index marks the total number of ampere-hours, or the total number of Board of Trade units which have passed through the instrument.

Edison Meter.—In describing the different meters, I will begin with the Edison meter, not only because it was the first to be used, but also because it has done a larger amount of useful work in central stations than any other meter. In its original form, as shown in the Paris Electrical Exhibition in 1881, it consisted of two copper plates suspended from the two ends of a balanced beam in a solution of sulphate of copper. A continuous current passing through from one plate to the other decomposed one plate and deposited copper on the other. This one eventually got heavy enough to tip over the balanced beam. This mechanical action had two effects, (1) it registered a unit on the counting mechanism, and (2) it reversed the direction of the current by means of a commutator; and now the current flowing through the solution in the opposite direction, the lighter plate received the copper deposit, and so the process went on continuously. It was not possible to pass the whole current in this way through the solution, because the resistance would be too great, unless we unduly enlarge the dimensions of the apparatus. Hence the depositing cell was put as a shunt on the main current. Several objections to this type soon became apparent in practice. (1) When the temperature of the air was high, the resistance of the solution diminished, while the resistance of the alternative metal path increased. Hence with high temperatures a greater proportion of the total current went through the meter. (2) It was soon found that a make-and-break, as necessitated by the commutator to produce reversals in the direction of the current, led to endless trouble, and the ingenious method of counting had to be abandoned. In the improved meter zinc is the metal employed, and sulphate of zinc the solution. The current always goes in one direction. Fresh plates are inserted as they wear away. These are examined once a month. To determine the consumption of electricity, the meter is carried away and the loss of zinc in the positive plate is weighed, and the consumer charged for a proportionate number of units of electric current; $\frac{1}{1000}$th of the total current passes through the zinc solution. In series with this solution (with the electrolytic cell) is placed a copper resistance, so arranged that with a rise of temperature the fall in resistance of the solution is exactly balanced by the rise in resistance of the copper, the alternative path being of German silver. Thus between 4° and 34°C. the same fraction of the current approximately passes through the solution. To prevent freezing an incandescent lamp is always kept burning in the case containing the meter during the months that freezing is possible. I have, through the kindness of the Edison-Swan Company, an Edison meter here. (Fig. 1.) In the lower division of the case you will notice the resistance in a zigzag form, and underneath that is placed a lamp which is used for the purpose of preventing the solution from freezing. There are holes at the side to allow a certain circulation of the air so that it may be maintained pretty constant in temperature all over. The shunt coil of copper wire is placed behind the upper compartments of the instrument and in series with the electrolytic cells.

The range within which the meter is said to be accurate within 3 per cent. is from fivefold to tenfold, according to the purposes for which it is in use—*i.e.*, if 1 ampere is the lowest current for which it is accurate, then 5 or 10 amperes is the maximum current for which it is accurate, though it will measure, of course, to a certain extent for greater or smaller currents.

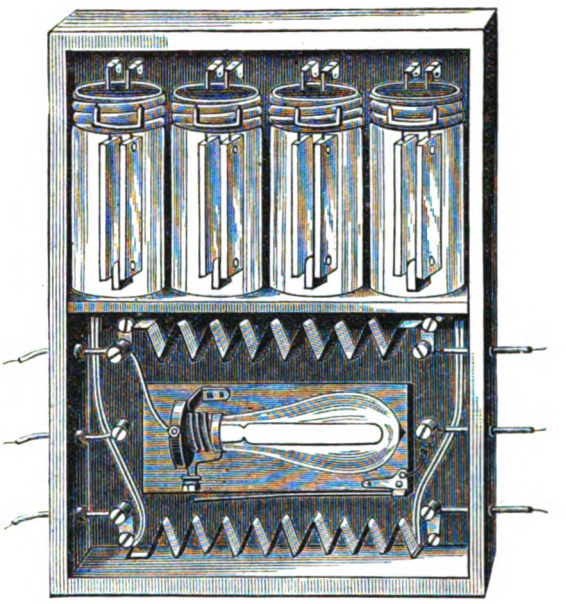

FIG. 1.—Latest Pattern Edison Three-Wire Meter.

Now, you may say that this is not exactly the kind of meter we require, because customers cannot check the weighings and are absolutely dependent on the good faith of the company supplying the electricity. It has also been argued that the shunt arrangement cannot be perfect with varying temperatures. I have heard both of these objections raised frequently, over and over again. I believe that there is a very general impression in this country that the Edison meter is not a satisfactory meter, and is not actually used in practice. I believe that there is a belief among a great number that in stations in America where the Edison meter is used, they never weigh at all, they simply guess at the bills and put them down. This is a total error; the instrument has been used in a very large number of central stations indeed. I agree entirely with every word in the very modest opinion which Mr. Edison expressed to me about it. He said:—"It is not an ideal meter, but it is simple and effective, and gives general satisfaction wherever it is used." I endorse this opinion (applause). But the managers of central stations where it is used have given me higher estimates still of its value. They say that customers are all quite content with the manner of reading it. As to accuracy, many customers have kept accurate tally of the lamp-hours which they have consumed, and compared it with the charges by meter, and have often come within 2 or 3 per cent. At the splendid central station at Milan, which I lately visited, this meter is in constant use, and is much appreciated by the company. They say that the expenses of maintaining the meter department are not large when the whole thing is well organised. The total number of ampere-hours sent out from the station, as measured by the ampere-meters, agrees with the meter

Digitized by Google

accounts within 3 per cent. This station, which I have carefully inspected, is an admirably conducted one, and embraces three systems—the Edison low-tension, the alternating high-tension, and the Thomson-Houston arc-lamp systems. I think there is no town in Europe where the electric lighting of the streets is so universally good as in Milan. The Thomson-Houston arc lamps are distributed through nearly all the leading thoroughfares of the town. It is difficult to walk in the principal parts of the town a distance of a few hundred yards without coming in sight of an arc lamp. The result it is needless to speak of to those who have ever appreciated the benefit of a town lighted by arc lamps at night. The charm of that light, when well distributed over a large district, is incalculable. It cannot be described. I remember well four years ago Mr. Preece when he came back from America after the British Association had been over there, describing the depressing effect of driving through London after one had been accustomed to the arc-lighted streets of America (applause). There is an effect on the system which is most marked, which every person who has ever experienced the benefit of living in an arc-lighted town has felt, an effect on the system of having a really pure and good light, not to mention the benefits of arc lighting to all the requirements of a town, and to the orderly manner in which a town is conducted, its cleanliness, and everthing else. I cannot account for the fact that in this country the arc light has been so much neglected in our streets, and I do trust that with the revival of electric lighting, which is coming on now, street arc lighting will be brought within the cognisance of the British public, as it is within the cognisance of other nations all over the world (applause.)

Ferranti Meter (Fig. 2.)—The next meter which I wish to describe is that of Mr. Ferranti. There is a drawing of it on the wall. This meter is so beautifully simple in its principle as to please one at first sight. It is founded on the principle that when an electric current passes through a fluid which is placed in a magnetised space, the fluid tends to move in a direction perpendicular to the current and to the magnetic action. Here is an iron column, D in the figure, with a hollow in its centre,

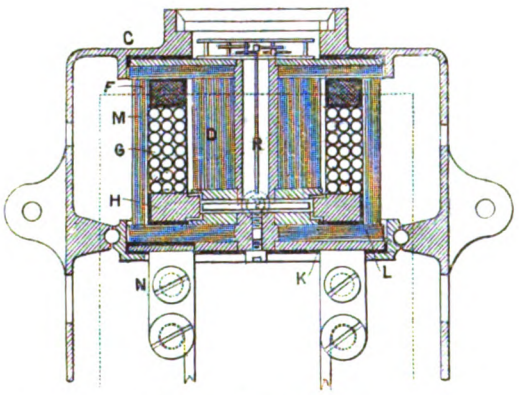

FIG. 2.—Ferranti Meter.

containing a rod, R, on the top of which is pivoted an arbor attached to the counting mechanism. This central iron cylinder is surrounded by wire coils, G, which are shown in section, and round the coil of wire is an iron casing, M. Thus, when an electric current passes through this coil, the central parts have one polarity, we will say North, and the outside casing has a polarity, which in that case would be South. Within the magnetic field is a layer of mercury, H, in which there is an extremely light delicate float attached to the rod R. Mr. Ferranti experimented to a great extent until he attained the shape which was found the most effective and to give the most accurate readings. This float is connected by the rod R with the arbor communicating with the counting mechanism. The current enters at the terminal K, and passes through the mercury to its circumference, meanwhile crossing the magnetic field. It then goes through the coils of wire that surround the magnet and goes out at the other terminal of the meter. The mercury, therefore, has a current passing through it from the centre parts to the periphery, and it is also in a magnetic field, and consequently it tends to move in a direction at right angles to the magnetic action, and at right angles to the direction of the current—that is, the liquid tends to circulate round the central vertical line, and in doing so it sets the float in motion and causes the mechanism to rotate (applause.) I should add, that the shunt coil at F is employed to give the field an initial value independent of the current, and which thus tends to correct for the error introduced by the friction of the wheel train.

The original instruments were intended for currents continuous in direction, and the magnets were excited by the electric current to a moderate amount, so that the magnetism was proportional to the current. Now the moving force is proportional to the magnetism, and it is also proportional to the current which is flowing through the mercury, and since the magnetism is also proportional to the current it follows that the moving force varies as the square of the current, and the fluid friction varies approximately as the square of the velocity. Consequently, the condition which I alluded to a short time ago is here fulfilled, and we ought to expect that the velocity would be proportional to the quantity of current passing. Of course the law I have spoken of is only true as a sort of approximation. The friction of the indicating mechanism is not proportional to the square of the velocity, and consequently that affects the result. The number of rotations made by the mercury is indicated by the rotation of a float of special construction, resting on the mercury, connected by a spindle, with a train of wheelwork which indicates the total number of revolutions. The meter has also been adapted for observing alternating currents, and is rendered more delicate by having an additional shunt winding of very high resistance. This shunt is put in multiple arc with the lamps on the two mains of the house supply. The friction of the wheel train is reduced to a minimum by employing the finest and lightest mechanism which can possibly be constructed. I am sorry to say that Mr. Ferranti has not been able to furnish me with any tests or specimens of his new alternating-current meter, as he is even now introducing some more improvements. I am told the range is about 50-fold, and that it is very accurate. I may mention, in praise of Mr. Ferranti's ingenuity, that both Mr. Edison and Mr. Weston, in America, two of the most prolific inventors, tried to work out a similar instrument, and found it ineffective. They both described to me their attempts at this, and were quite astonished on hearing of the success which had attended Mr. Ferranti's efforts in this direction (applause). The chief difficulty which these experimenters met with was one which, until Mr. Ferranti attacked the problem, has been taken as a universal fact, viz., that mercury is unsuited for a permanent contact. They found that the mercury got covered with a film or powder which interfered with its free movement. I am informed that in Mr. Ferranti's instrument, where enormous care is taken to purify the mercury, there is no such action at all.

(To be continued.)

THE PHYSICAL SOCIETY.

At the last meeting of the Physical Society, held on January 26th, Prof. S. P. THOMPSON read a Note on

"A Relation between Magnetisation and Speed in the Dynamo Machine."

In a Note on "The Conditions of Self-Excitation in a Dynamo Machine," communicated to the Society May 12th, 1888 (see *The Electrician*, May 18, 1888, p. 43), the author arrived at the conclusion that in a well-built dynamo, where C is the number of conductors counted round the periphery of the armature, n the number of revolutions of the armature per second, N the whole number of magnetic lines (in C.-G.-S. units) which traverse the armature, i the current in the circuit, S the number of convolutions in series with the main circuit, ΣR the sum of the electric resistances (in C.-G.-S. units) of the circuit in which the E.M.F. operates, and $\Sigma \rho$ the sum of the magnetic resistances in the magnetic circuit, the equation of E.M.F. is

$$n C N = \Sigma R i,$$

and the equation of magneto-motive force is

$$4 \pi S i = \Sigma \rho N,$$

from which by multiplication together

$$4 \pi S n C = \Sigma \rho \Sigma R,$$

or the product of the magnetic and electric resistance is constant for a definite speed of rotation. He now desired to call attention to the fact that the last equation gave the means of determining the limit of self-excitation when the speed was altered by a definite amount, for the equation may be written

$$\frac{4 \pi C S}{\Sigma R} = \frac{\Sigma \rho}{n},$$

showing that self-excitation will continue until resistance to magnetism is proportional to the speed.

Prof. E. F. HERROUN then read a Paper on

"The Divergence of Electromotive Forces from Thermo-chemical Data."

The author pointed out that it had been remarked by many physicists, including Favre, Julius Thomsen, Braun, Helmholtz, Willard Gibbs, Wright and Thompson, and others, that the observed

Digitized by Google

E.M.F.s of many voltaic cells do not agree with the values calculated from thermo-chemical data, and stated that the object of the investigation described in his Paper was to throw some further light on the subject.

Cells of the Grove or Bunsen type, in which nitric acid is reduced by the evolved hydrogen, were excluded on account of their non-reversibility and the complicated secondary actions which occur in them, and the investigation was confined to cells of the Daniell type.

It has frequently been assumed by physicists, and notably by Helmholtz in his Paper,* that the divergence between the observed and calculated values of the E.M.F. is to be explained, in the case of cells giving a deficiency of E.M.F., by a portion of the chemical energy appearing as heat in the cell, and in the case of cells giving an excess of E.M.F. by their partly working at the expense of the heat of surrounding bodies. The author objects to this explanation that the E.M.F. of a cell, such as the Latimer-Clark cell, which is in excess of its calculated value, ought to increase with increase of temperature, which, however, is not the case. The author describes a long series of experiments made with the following pairs of metals in contact with their own salts :—

Cadmium and copper.	Lead and zinc.
Mercury and copper.	Cadmium and iron.
Silver and copper.	Tin and copper.

The range of the experiments was greatly limited by the fact that very few cells could be found which even approximately fulfilled the conditions required, viz. :—Tolerable freedom from polarisation, perfect reversibility, low and constant internal resistance. The author finally arrives at the following conclusions :—

1. The primary factor in determining the electromotive force of a voltaic cell is the relative heat of formation of the anhydrous salts of the two metals employed.

2. That this E.M.F. may set up chemical changes of a different direction and character from those predicable from the heat of formation of the dissolved salts.

3. That the E.M.F. set up by (1) may be, and usually is, supplemented by the energy, or a portion of the energy, due to the hydration or solution of the solid salts, and may have values which accord with the heat of formation of the dissolved salts.

4. That in those cases in which there is no chemical attraction, or a very feeble attraction between the water and the salt, the negative heat of solution is derived from sensible heat, and is not supplied by the free energy of the chemical change. All cells in which such salts are employed opposed to zinc should have negative "thermo-voltaic constants," and evolve heat when they send a current forwards.

5. That when metals whose salts have purely negative heats of solution are opposed to metals whose salts they can replace the E.M.F. set up is *in excess* of the total thermal change. Such cells, therefore, absorb sensible heat when worked forwards.

6. That taking the foregoing facts into consideration no cell exists which can furnish an E.M.F. in excess of the free energy of the chemical change ; *i.e.*, which can convert sensible heat into electric energy, when working at uniform temperature.

7. That certain metals have a tendency to form films of sub-salts on their surfaces, the formation of which, giving rise as it does to a different thermo-chemical reaction, naturally furnishes an E.M.F. which does not correspond with the values calculated from the heats of formation of their *normal* salts.

8. That the electromotive force of a voltaic cell furnishes a more accurate measurement of the "free energy," and therefore of true chemical affinity, than data derived from calorimetric observations.

LEGAL INTELLIGENCE.

In re Gaulard and Gibbs' Patent.

COURT OF APPEAL.—MONDAY, JANUARY 21.

Sir HORACE DAVEY, in opening the case for the respondent, said that he was yet at a loss to understand what the other side were prepared to say was the invention they supported. The nature of the invention as described in the provisional specification was one thing, as described in the amended and complete specification it was another, as described by Mr. Aston it was a third, and the invention as described by their witnesses was another thing still. In the course of Mr. Aston's long argument he had not heard one single attempt to grapple with the difficulty which was admitted by Dr. Hopkinson, Prof. Adams and Prof. Forbes in their evidence, namely, that the patentees had not attempted to set forth in their specification what were the essential features which they claimed as a speciality of their secondary generators. It was put in the forefront of the cross-examination, and both Prof. Forbes and Dr. Hopkinson admitted that they were unable to say that the patentee had stated in the specification what he considered essential to the working of his system, or what were the specialities upon which he relied. He (the learned counsel) proposed to show, first, that there were non-conformities between the amended specification and the provisional specification. The invention which was described in the latter was a wholly different thing from that described and claimed in the complete specification, and that the complete specification was wider than the provisional, inasmuch as it was less special. His second point was insufficiency of specification. By that he meant, not that a workman or an electrician could not construct the system from the description given, but that the patentee had not stated what was new and what was old, or what, perhaps, was of more importance, what was essential and what non-essential—that he had put in a wide, general claim, without sufficiently ascertaining (to use the words of the Statute) what his invention was. His third point was that the system of distribution which was claimed, and which the claim was intended to cover, was not novel at the date of the patent. He relied principally upon the publications of Jablockhoff (as expounded in Du Moncel's *exposé*), Edwards and Normandy, De Meritens (under the name of Johnson), and Marcel Deprez (under the name of Imray and Harrison). Having regard to the state of knowledge as disclosed in these publications, there was no room for a patent containing the wide general scheme contained in the present patent. Of course there was ample room for an invention to improve on any details, but there was no room for an invention such as that which was claimed of the whole system as a principle. He was unable, and (which was much more important) Sir William Thomson was unable, to see the slightest distinction between the so-called invention claimed here and that which was described in the prior publication of Edwards and Normandy.

To deal with the first point, that of nonconformity, the nature of the invention described in the provisional specification was this : A system of distribution by which an unlimited number of lights might be produced without any loss of energy in the primary wire, and that the patentee thought he had attained by means of a special construction of secondary generators or induction coils. If that had been aptly described, and if the invention had been successful, it would have been of marvellous value and power. The invention was not a general system of lighting by means of sending a current through a primary wire, which by induction coils could be utilised for lighting lamps or for motive power, but it was a system by which they could do that without any loss of energy in the primary wire. In a vernacular form the nature of the invention was this—that it enabled you to eat your cake and still have it. The principle which was the basis of this system was stated by the patentee as follows :—"When an electric current approaches or recedes from a circuit of solenoidal form, it determines in this latter a current of induction without in any way qualifying the value of the primary current." The obvious and real meaning of those words was that the current of induction was determined in the induced circuit, the secondary circuit, without the value of the primary being in any way modified—in other words, that there was no loss of energy in the primary wire when a current of electricity was induced in the secondary coil. If that were true it would amount to something like perpetual motion. The witnesses for the other side said it was not true, but that it might mean "without the operator modifying the current." The witnesses had to give a strained, unnatural, and forced construction to almost every word of the provisional section in order to make it sense. The patentee's idea seemed to have been that because there was no communication between the primary wire and the secondary wire, therefore the current suffered no loss of energy, no modification, in the primary wire, in consequence of a current being induced by means of induction coils, and therefore the number of lamps which might be lit was unlimited. If there was a loss of energy at every installation or station, the number would be limited when your energy was exhausted, but if there was no loss of energy in the primary wire, they might have as many installations on as the primary wire was long enough to bear. The patentee claimed to achieve this end by the special construction of his secondary generator or induction coil. When a patentee stated in the provisional specification the principle involved in his system, he was not at liberty in his complete specification to give the go-by to that and claim a general principle of which he had given a particular example in his provisional specification. Mr. Aston had said over and over again that the essence of this invention was the use of high tension in the primary current and low tension in the secondary current. From beginning to end of the provisional specification there was nothing whatever about the tension in the primary or secondary current. There was not one word as to the ratio, or proportion, or relative strength of tension in the wires, and it was not stated that, as part of the invention, the primary wire was to have high tension. Coming to the amended complete specification, he submitted that it abandoned the special characteristics of the invention as described in the original, and claimed the general principle of a combination of alternating currents of high tension with secondary generators for the purpose of producing light and power. There was omitted from the amended specification that which the patentee in the provisional specification had stated to be the principle which was the basis of his system of distribution. Not a word of the following was in the original : —"We take an alternating-current dynamo machine, constructed in such a manner that the resistance of the inductive system is greater than that of the external circuit uniting its two extremities ; but we do not use or desire to use the alternating-dynamo machines that produce currents other than the currents of high tension." He submitted that a man could not take up a patent for a dynamo of high tension unless it was a particular construction of dynamo which produced high tension. There was not a word in the amended specification as to the secondary current being of lower tension, nor was it stated how many windings of the secondary coil there should be on the induction coil; on the contrary, it was stated that the apparatus con-

* "Ueber die Thermodynamik Chemischer Vorginge." "Sitzungsberichte der Akademie der Wissenschaften zu Berlin." 1882. Translated in 'Physical Memoirs" (published by the Physical Society, Vol. I., part 1.)

Digitized by Google

stituting the induction coil might be arranged either for the purpose of increasing the tension or for increasing the quantity according to the demands of the consumer. "To sum up, we claim, in accordance with the law, the privilege of exclusively working our process of distribution characterised by the following points, above explained—the employment of an alternating current of high tension"—not an alternating current produced in any mode, but "an alternating current of high tension"—"for the generation on a number of secondary generators of induced currents individually utilised either for the production of light or motive power." His learned friends had talked about the Gaulard and Gibbs system, but when he came to examine what they meant, it was not one single one of the special heads mentioned in the specification, it was merely this general combination of an alternating current of high tension with secondary generators of any construction used for the production of light and motive power. They were right. The claim in the patent was for the combination of an alternating current of high tension, however produced, with secondary generators, of whatever construction, for the production of light and power by means of the induced current. The marvellous power of producing light or motive power at an unlimited number of stations without any loss of energy in the primary wire was altogether omitted in the amended specification, but, according to his contention, that was the speciality of the provisional specification. The invention was enlarged by being made less special, because it was made to include not only a system of distribution which (if true) had that great economical value, but *all* combinations of alternating currents of high tension with secondary generators for the production of light and motive power. A man was bound to state the nature of his invention in the provisional specification; in the final he might specialise it, but he could not drop one of the essential constituent elements in the combination in the provisional. This was the first case he had seen in which the whole of the provisional was taken up in stating the principle which was the basis of the invention; and in which the patentee, when he came to the complete specification, threw that overboard in the most marked manner by striking it out on amendment. He submitted, therefore, that the patent was bad for nonconformity of the final specification with the provisional.

With regard to the second point—of insufficiency of specification—what was the invention claimed? It was a perfectly general claim, as was shown, he contended, by the evidence of Dr. Hopkinson, Mr. Swinburne, and Prof. Adams. Putting the system into practical effect, it might be admitted at once that one of its merits was that it gave a means by which wires of low tension could be used in houses where they wanted low-tension currents. But that was not the question; the question was, what the patentee had described and claimed. Assuming the invention to be, as Dr. Hopkinson described it, for a special class of secondary generator or induction coil, had the inventor stated what was or was not essential, what was or was not the particular specialty in his secondary generator which he wished to employ? They attached so much importance to this that it was put in the very forefront of Dr. Hopkinson's cross-examination. That gentleman said there was nothing in the specification to show which things were and which were not essential to success. Prof. Forbes said the patentee did not point out any essential features. Assuming a secondary generator or induction coil of a particular type or class to be claimed, on the showing of both those gentlemen the class or type could only be ascertained by the two examples given by the patentee, and there was nothing in the specification which told one which features or characteristics or elements of the two descriptions were considered to be essential or non-essential. He had not warned the public off, and told them what they were to use and what not, nor had he told the workman what were the essential features, and he did not inform the world (as he was bound to do) what the essential element was; in fact, the specification wholly failed to inform those who desired to put it in force what they might do and what they might not do in order to produce the desired result. Mr. Aston, he thought, was ultimately inclined to say that it was a combination of an alternating current of high tension with a secondary generator with a divided core. Had the patentee said that a divided core was necessary? A workman would make it with a divided core; but why? Not because he was told so on the face of the patent, but because every practical core at that time in the market or known to makers had a divided core. Dr. Hopkinson had said that every practical induction coil at that date, in 1882, had a divided wire; so there was no speciality whatever in it. With one exception, all the anticipations were described and used as divided cores. It had been said that Jablochkoff did not describe a divided core; but in Du Moncel's *exposé*, which was as good a publication as the patent itself, it was undoubtedly a divided core. Sir William Thomson said that any ordinary induction coil known at the time would work as well as those described in the specification—in other words, there was no speciality; and in reply to another question he said the induction coil described by Gaulard and Gibbs was not the best form known for the purpose, but so far as it deviated from the ordinary form it was not an improvement, but the reverse. They had been told that the Gaulard and Gibbs system had been applied in a hundred towns in America, at the Edgware-road and at the Grosvenor Gallery. In every one of those cases, according to undisputed evidence, the secondary generators were not of the construction mentioned in the patent, so far as the description in the specification differed from an ordinary induction coil.

In regard to his third point—that of anticipation—he said boldly and fearlessly that Edwards and Normandy, in every singular particular which was claimed in the amended section, was an anticipation of the Gaulard and Gibbs patent. It might be extraordinary that Sir William Thomson at the time he gave his lecture in York was not aware of the prior publication of Edwards and Normandy, but that did not alter the fact. Sir William Thomson was not a patent agent, and he had a great deal of other work to do besides reading patents. He was bound to say that Sir William Thomson did not think so highly of Gaulard and Gibbs, or of Edwards and Normandy, as some other people did. Gaulard and Gibbs were claiming a monopoly of the principle of transformers, but if that principle had been previously disclosed they could not patent it. For what did they claim a monopoly? Not for an invention, but for its exploitation, because rich men had commercially developed a system which had been previously described by humbler men, but men of great distinction, in advance of their time. It was preposterous. Let them have all the merit which attached to those who see the value of an idea and carry it into practical commercial success, but they cannot therefore claim to be monopolists of the idea or the principle itself. He defied anybody to draw any distinction between the system described by Edwards and Normandy, and that described by Gaulard and Gibbs. The patent was bad for want of novelty. Dr. Hopkinson had utterly failed to distinguish Jablochoff's system from the plaintiffs', and if he (the learned counsel) had not been told the contrary, he should have thought that Gaulard and Gibbs must have had Edwards and Normandy's specification before them—even in its errors the latter had anticipated Gaulard and Gibbs. Absolutely no sound distinction could be found; in Sir William Thomson's words, Edwards and Normandy required no modification whatever—it was exactly, even in its mistakes, Gaulard and Gibbs's system. There were the alternating current, the secondary generator, the divided core, and (on the testimony of Dr. Hopkinson) passage from high to low tension in the description of Edwards and Normandy. What was there in the plaintiffs' specification which was fuller than that in any of its details? The only distinction that Dr. Hopkinson could draw was that Edwards and Normandy did not get their current from an alternating machine. They could not get a patent for a particular instance of what had been aptly and sufficiently described in general terms. They might get a patent for an improvement, and they might be entitled to a monopoly of that improvement, but they could not get a patent for telling the world, or telling the previous patentee, the best mode of using his patented machine. Then with regard to De Meritens, with the exception of the faulty form of induction coil, Dr. Hopkinson could not point out any distinction between it and Gaulard and Gibbs. Except for the source of the alternating current there was nothing in Deprez which differed from the plaintiffs' combination. If Deprez had come after Gaulard and Gibbs, would anybody suggest that he could have defended himself from an action for infringement because he did not get his high-tension alternating current from a dynamo? In conclusion, he contended that after the disclosures in the instances he had cited, there was no room for any one to take out a patent for the principle of a combination of alternating currents with secondary generators as a means of lighting or of giving motive power by induced currents. Let Gaulard and Gibbs have the full benefit of their enterprise, but do not let them seek to arrogate to themselves a monopoly of something which they did not invent, of something which was as old as the year 1877-78, and which had been fully and adequately described in Edwards and Normandy.

At the close of the learned counsel's address the Court adjourned.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *January 19th*, 1889.

Looking back over the past year, perhaps the feature which most arrests attention in the industrial department of electricity has been the utilisation of electric power both in manufactures and in street railway work. The demand for electric motors is now greater than it has ever been before, and there is every reason to believe that 1889 will witness a tremendous extension of their use. As an adjunct to central stations of all sizes stationary motors are now looked upon as indispensable, and nearly all the large companies in the leading cities have their regular rates for motor service just as they have for arc and incandescent lamps. Owing to the greater number of arc circuits there has perhaps been more opportunity of introducing constant-current motors, and a very large number of these are now running in New York, Boston, Philadelphia, Chicago, Baltimore, San Francisco, Detroit, and other cities; but the incandescent central stations have also been called upon to do a large proportion of the work, especially in New York and Boston, where the sale of power is understood to have added materially to the income of the local Edison Companies. Up to the present time no very great stride has been made in the establishment of power stations, pure and simple, but there is promise of some interesting work of this nature. For instance, in this city where independent power stations on the Daft and Sprague system are already operating, the "C. and C." Motor Company propose to try an important experiment. In other words, they are about establishing a new factory for the manufacture of their well-known motors, of which about 500 are in use in this city alone, and probably some 5,000 all over the country, and in connection with their factory they will equip a building for miscellaneous manufacturing purposes with electric power,

Digitized by Google

no other provision for power being made. Small motors will be put in on each floor, operated from the generating plant in the basement, and these motors will be put just where the convenience of the customer on any floor may demand. In addition to this, the company will run out wires through the immediate vicinity, and there furnish power to anybody who may want it. The building which the company have secured for this purpose is a fine one, and as the matter is in capable hands I look for a very successful outcome of this experiment, which will go far, I think, to show how far much better electric power is than any other for the wants of small manufacturers.

Turning to electric railways, the development has been, if anything, more remarkable than that which may be noticed in the stationary motor department. Just about a year ago, there were about a score of roads operating in this country, and about as many more were projected. None of these roads were of any very great magnitude or importance, and many of them were operated with motors and cars that might well be described as relics of a barbaric age in the art. The twelve months have seen a wonderful revolution. The number of roads running has increased from a score to over 50, and at the present time the number of roads actually building, contracted for, or for which companies are formed, is over 75, so that should they all go into operation this year, as may be confidently expected, we shall have, at the end of 1889, no fewer than 125 electric railroads operating in this country. Many of these roads will be of considerable magnitude; several of them have already a length of from 10 to 14 miles, and the equipment often consists of 15, 20, or 30 cars. There has been a great improvement from time to time in the quality of the work. The motors have become better fitted to the demands made upon them, line construction has been greatly improved, and the whole business may be said to have taken a respectable shape. A year ago it seemed hard to convince street railway men that electricity was more than an experiment, and that it was worth while to put in a reasonable sum of money for the solid construction of an electric equipment. The consequence was that the work was but too often done in a slipshod, cheap and unsatisfactory way. But now, as instanced by the roads in Washington, Cleveland, and Boston, as well as other places, the construction is of a very substantial character, and even goes so far as to be ornamental. General satisfaction seems to be felt by the public where these roads have been installed, with their light and tasteful appliances, as compared with the gloomy and clumsy looking elevated roads with which we are afflicted in New York. In connection with the elevated roads it will be remembered that Mr. Daft has been giving successful demonstrations on the Ninth Avenue road, and it is expected that some definite step will be taken this year by the management as a result. It is further to be borne in mind that the Julien Electric Company have done some very good work in the exploitation of the storage system, and they certainly have won the goodwill of the public by the manner in which they have shown that luxurious street car travel can be put within the reach of everybody. Storage car work is also going on in St. Louis and Sacremento and other places; but the rush in this particular section of the field has not been quite so great as was expected. Nearly all the roads of which I have spoken are operated on the overhead system, but the Bentley-Knight conduit system has been given a trial in connection with the new work of the west-end railway in Boston, and it has just been laid down in Fulton-street in this city, the construction of the conduit being likely to be finished in a day or two. Owing to the unusual mildness and openness of the winter, electric railway construction work had, in fact, been continued much further through the cold months than was anticipated, and in the Pacific and Southern States, where frost has not to be combated with, the work is going on very actively without any intermission. With regard to the roads in the north, it was feared that perhaps they would make a bad show when subjected to the strain of wind and snow, but wherever the opportunity has arrived they have stood up nobly. At St. Joseph, Mo., a few weeks ago, during a terrific storm, when every other electric service in the city was suspended, the electric roads went on with their business in the most matter-of-fact and re-assuring way, and reports of a similar nature now come from Davenport, Ia., where, during a typical blizzard, the Sprague road kept on running in spite of the gale, and through snow averaging from 6in. to a foot.

It might be surmised that all this work naturally creates a demand for men to carry out the contracts. This is the case, and it very often happens that the work has be done by men who are entirely new to the business. That they can do it all speaks volumes for the advances that have been made in simplifying and systematising the apparatus and appliances. In running electric cars, men are taken direct from the horse cars, or else are practically picked up out of the street and put at once to work, with very little instruction. In the matter of line construction and central station equipment perhaps more care and experience are required, but here, again, very fair success has been obtained with the labour employed. An interesting evidence of the extension of electric industries was afforded recently in Chicago, where it was necessary to wire up the Opera House for some 400 lights in less than a week. To carry out the contract it was necessary to employ some fifty or sixty workmen, and owing to the activity in electric matters generally, it was not easy to obtain such a number. Still, they were recruited, and the work was satisfactorily performed and completed in less than three days. This little incident may be regarded as showing how rapid has been the development of the industry, for I do not believe that it would have been possible two years ago, or even a year ago, to get that amount of work done in such a hurry. Of course there is plenty of room for improvement in the quality of the work, but highly praiseworthy efforts are being made in that direction, such as those, for instance, of the New England Electric Exchange, and the standard of the requirements in performance is being steadily raised.

Another feature in this connection worthy of mention has been the establishment of a number of firms of electrical engineers who stand ready to undertake the designing, construction, and equipment of plants for electric light and power. While a great many companies, perhaps all, find it advantageous to do their own work of this character, it is very often convenient to be able to turn it over to some firm, the members of which have a reputation and of whose ability to carry out the contract there is no doubt. These firms are now to be found in all parts of the country, often serving as special agents of the various systems, and in many other cases standing ready for all the work that may come along, no matter what may be the system. The development of electric lighting has called into existence this class of practical experts, and in one way and another they are rapidly becoming a mainstay of the business as the men to whom we must look for good advice to local parties intending to put in electrical apparatus, and for good work when the choice has been made. The more recent development of electric railroad work has created another field in which electric engineering can display its abilities, and hence the number of such firms bids fair to increase.

One of the largest gatherings that has attended the meetings of the American Institute of Electrical Engineers was present on the evening of Jan. 8 to hear a Paper read by Mr. E. G. Acheson, of Pittsburgh, entitled "Lightning Arresters and the Photographic Study of Self-Induction." The Paper, which was of considerable length, was based primarily upon experiments which had been made for the protection of lead-covered underground cables from lightning discharges, experience having shown that the insulation became punctured in a most unaccountable way. To these were later added experiments which were made in the light of the results obtained by Dr. Lodge on static discharges and his now celebrated "alternative path." Mr. Acheson first described a number of experiments similar to those made by Dr. Lodge and others, which he varied to conform to the conditions to be found in underground cables. In general, his results may be said to correspond fairly well with those of Dr. Lodge as regards the relative size of the "A" and "B" spark, and with the use of iron and copper in the alternative path; but Mr. Acheson differed entirely from Dr. Lodge in the explanation of the results obtained and in the nature of the "B" spark. Generally stated, Mr. Acheson holds that the wire shunt at the "B" terminals is not an alternative

Digitized by Google

path in the sense that Dr. Lodge assumes. The latter's argument is that the self-induction in the wire creates such a high self-induction as to offer such a virtual resistance that the spark prefers to jump across the air rather than pass through the wire. In other words, the wire is put into a temporary state of enormous resistance, pure and simple. Mr. Acheson's theory however, differs from this in that he asserts that the "B" spark is not produced direct from the discharge of the jar, but that it is a secondary spark induced by the self-induction of the wire shunting the "B" terminals; in other words the spark "B," according to Mr. Acheson, has an independent origin from that of "A." In order to strengthen his position in this theory, Mr. Acheson has had recourse to photography, by means of an apparatus consisting of a perforated revolving screen, with which he obtained images of both "A" and "B" under varying conditions. The theory which he has assumed Mr. Acheson considers confirmed by the fact that while the "A" spark is shown by photography to be instantaneous in all cases, leaving a clearly defined image of the aperture on the sensitive plate, the "B" spark, on the contrary, under the conditions is found to have a ghost like tail following it, which would seem to show that the "B" spark is prolonged, and that there is a time interval between the spark "A" and the end of spark "B," due to the time required for the production of the self-induced current in the wire shunting the "B" terminals. Mr. Acheson further strengthens his theory by a number of other considerations which would lead me too far; but the results he obtained are certainly worthy of consideration by all interested in this subject. The paper is full of suggestions, and barely touches the subject, so that we shall no doubt hear more in the future.

CORRESPONDENCE.

THE PHYSIOLOGICAL EFFECTS OF ALTERNATING CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The letter of your correspondent "Telegraphist" and recent American notices prompt me to call attention to the fact that the resistance of the human body to alternating currents is only about *half* what it is to continuous currents. (See *The Electrician*, April 30, 1886, p. 503.)

This curious fact was first pointed out by Dr. W. H. Stone in his Lumleian lectures before the Royal College of Physicians in April, 1886, and has been confirmed by others since.

In practice here I have many times proved it, and have also frequently found that patients (and healthy visitors also) who can bear, say, 20 or more milliamperes of continuous current without pain, are utterly unable to bear 1 milliampere of the alternating current of the secondary circuit of an induction coil.—Yours, &c.,

H. NEWMAN LAURENCE.

The Institute of Medical Electricity (Limited),
January 29, 1889.

TELEGRAPHY WITHOUT WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to your editorial comments on my letter on the above subject in your last issue, I should like just to point out that whereas Mr. Preece, in the account of his own experiments which he read before the British Association at Manchester, said:—"The disturbances due to the mixed working currents on our telegraphs cannot be appreciable beyond 450 feet," in the experiments described by myself this intervening distance was increased to very nearly double this amount without the inductional disturbance becoming at all very faint, and this with a secondary wire only 110 yards in length.

Considering that the law of inverse squares applies, the above is, I think, worth calling attention to.—Yours, &c.,

A. A. CAMPBELL SWINTON.

66, Victoria-street, S.W., January 29, 1889.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. A. A. Campbell Swinton having invited me to hear the induction effects described in your last issue in Queen Victoria-street, which I had suggested were due to the proximity of one of our type-printing telegraph wires, I found that they were undoubtedly due to a Wheatstone automatic instrument. But from previous experience of the effect of induction upon our City telephone wires, I am convinced that such powerful induced discharges could not be elicited from conductors 300ft. apart under any circumstances; but I beg to submit the following explanation of the phenomena:—The soil in the locality is dry gravel and sand. The earth connections are imperfect. The Post Office pipe being somewhat in the route of the earth, portion of the circuit between the two stations forms part of a derived circuit, consisting of gas, water and other pipes, and the ground itself. Throughout its length this pipe is subject to the influence of the Wheatstone alternations, which become perceptible in any part of the pipe which is insulated or partially insulated and unfurnished with a discharge path.

I am the more inclined to attribute the effects observed to this source, and not to direct inductive action, from the fact that our wire, which is parallel to both, and conveying alternate currents of greater strength than the Post Office wires, has so little effect upon the telephone wire that it requires some knowledge of the signals to detect the induction at all; and, on the other hand, the induction of the Wheatstone working is altogether unheard in our wire.

In a case of direct induction through 300 feet our wire should share with the telephone wire.

Another telephone wire which appears to run at right angles to the Post Office wire shows the same effects as Mr. Swinton's wire, both using the same earth.

I am aware that electrostatic inductive effects are visible in vacuum tubes at great distances from an electrical machine, being well visible at 30ft. from a 2in. spark machine, but the action is progressive, commencing after the passage of sparks, and continuing for some time after the last discharge. But electrostatic induction of this character is very irregular in its action, dynamically feeble, and will not produce signals sharp and clear like those obtained in the telephone wire.—Yours, &c.,

17 and 18, Cornhill, London, E.C., F. HIGGINS.
January 28, 1889.

ALKALINE ACCUMULATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to the inquiry of Mr. A. E. Greville in your last week's issue, I beg to say that, although local action in the gradual re-dissolution of the zinc no doubt takes place, it is so slow that it may be disregarded for ordinary periods.

In the case of the miners' lamp, there would not be a loss of 5 per cent. between the quantity of current put in and that taken out in twenty-four hours—a better result than any lead cell I have tried.

I am glad to hear of the experience of Mr. H. J. Coates, and beg to assure him that he need not fear any such accusation as he suggests.

Mr. Commelin and his assistants tried many positive plates of the kind described by Mr. Coates—probably with similar success—before they hit upon the present form which proved so surprisingly successful.—Yours, &c.,

P. BEDFORD ELWELL.

London, W.C., January 31, 1889.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: As one who has been much interested in the development of secondary batteries, and as the inventor of the mechanical system of production of porous metallic electrodes by the compression of metallic particles into a coherent mass, (Patent 5,196 of 1881), I should like to be permitted to ask, with reference to the letter from Mr. Coates in your last impression, wherein lies the similarity which he claims for his battery with that of MM. Dezmazures and Commelin? He speaks of similarity and then proceeds to show that none

Digitized by Google

exists. He used an amalgamated zinc plate. There is, as I understand it, no such thing in the Dezmazures battery, but instead an iron gauze, upon which zinc is deposited in the action of the battery. Mr. Coates says he used silver powder on a thin silver plate. This is distinctly a different thing from a plate formed by compressing silver powder into a coherent but porous silver plate, and the difference is as great as that between Faure's lead plate coated with powdered (red) lead, and the plates subsequently made of similar materials compressed into a coherent mass without any lead-supporting plate. If there is any real similarity between the battery referred to by Mr. Coates and that of M. Dezmazures, the former appears rather to have explained it away than to have disclosed it.—Yours, &c.,

London, January 28, 1889. W. Worby Beaumont.

THE AURORA BOREALIS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I have been much interested in Mr. Norman Lockyer's new theory of the aurora, to which you refer in the leading article in your last issue. You there remark that it has not yet been shown in what way the theory of the meteoric origin of the aurora accounts for the geographical distribution of the phenomenon. It occurs to me, however, to suggest that, owing to the known presence of iron in meteorites, it is quite reasonable to expect that they would be deflected towards the magnetic poles of the earth. As bearing on this suggestion, it would be well to inquire whether the coronal arc is centred over the magnetic or over the geographical pole, a question on which I have not noticed any statement.—Yours, &c., W. M. Mordey.

London, Jan. 24, 1889.

[Our correspondent's ingenious suggestion receives support from the fact that the coronal arc is undoubtedly centred over the magnetic and not over the geographical pole. This fact is explicitly stated by more than one writer who has witnessed the phenomenon from high latitudes.—Ed. *E.*]

CONSTANT CURRENT REGULATION.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I have read with no little surprise the remarks which have been made in the correspondence columns of your esteemed paper on "Mr. Edmunds' Method of Maintaining Constant Current," and I beg permission to say a few words on this subject. About two years ago I had occasion to run a series dynamo used for the supply of a number of series lamps and driven by a separate steam engine. The regulation of the dynamo not being quite satisfactory, I threw off the governor belt and let the engine itself do the regulation for constant current. As the engine was rather far from the boiler the regulation was only perfect within small limits, but quite sufficient for this special case. Mr. Atkinson, representing Messrs. Goolden and Trotter, was present at the time, and will, I think, remember the facts. You have yourself kindly published a report which I sent to you later on in *The Electrician*, May 6th, 1887, page 560.

At about the same time Mr. Edmunds wanted to sell to me Hochhausen dynamos, which he claimed offered the best means of obtaining constant current. I told him then that I preferred to drive each dynamo from a separate engine, and I explained to him at great length why an engine without a governor would automatically adjust its speed so as to maintain a constant current. This explanation was then perfectly new to Mr. Edmunds, according to his own statement to me.

Much better results than those mentioned in *The Electrician* in May, 1887, have been obtained by me later on. In one case a well built engine, which was quite close to the boiler, was driving a Brush dynamo for the supply of 18 arc lamps and 24 glow lamps of 6 volts each. When all the 18 arc lamps were switched out at once, the current only rose from 10 to 11½ amperes.

I shall not enlarge on this subject at present, as I have had in my desk for some time already a Paper on this matter and several others, the publication of which has been delayed by some additional new matter on which I am still engaged

I may add that, according to information which I have lately received, the credit of having first explained the theoretical principles on which this regulation for constant current is based is due to Marcel Deprez, and, furthermore, the method is already fully explained in the excellent book of Silvanus P. Thompson on "Dynamo Electric Machinery," 1st edition, page 100.—Yours, &c., Alexander Bernstein.

Hamburg, Mühlenkamp, January 28, 1889.

[We should like to point out that Mr. Edmunds, at the Institution of Electrical Engineers, expressly credited Mr. Bernstein with having been the first to employ the method; Mr. Edmunds, moreover, did not himself attach his name to the method, and perhaps we ought not to have allowed our correspondents to do so.—Ed. *E.*]

RED WIRE *VERSUS* BLACK.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In specifications for wiring it is frequently stipulated that red wire be used for the leads and black for the return.

Although there may be some slight advantage in this arrangement, we feel sure that no one would wish to insist upon its adoption at a sacrifice of efficiency.

We have invariably found, especially in damp situations, that the red wire shows a marked inferiority both in insulation and durability, and we shall be glad to hear whether this is confirmed by the experience of other electric light contractors.

We may add that this applies to wires of all manufactures that we have employed.—Yours, &c.,

Drake and Gorham.

ETHER RESISTANCE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Permit me to offer the following suggestion as a reason for gases or liquids of great mobility presenting little resistance to a moving body:—

Resistance to motion implies accumulation of heat energy in the moving body: and the converse, that a body would move free of resistance if the receptivity of the surrounding medium were such as to prevent any rise of temperature, is quite conceivable. This property of receptivity is dependent on molecular velocity and frequency of impact. A case at instance is that of hydrogen and other light gases of high molecular velocity, absorbing heat with greater rapidity than those of heavier molecular construction. If the molecular masses constituting ether are exceedingly small, they must, to have the same momentums or temperatures as ordinary gases, have exceedingly high velocities, and the relation between their velocities and that of the moving body should determine the efficiency of their receptive quality under those conditions. It must also be remembered that as ether permeates all known bodies it has great facility for impressing its influence on such.

If two such gases as hydrogen and oxygen be contained in vessels of equal volumes, under identical conditions of temperature and pressure, they will, according to the now generally accepted hypothesis, possess equal numbers of molecules, and the momentums of these molecules will be the same in each case; but oxygen has sixteen times the density of the hydrogen, hence its molecules must be of such a size as to ensure the same frequency of impact during any interval of time as the hydrogen. We have, then, the same amount of energy per unit of cubic content in each case, and we should expect the same resistance in each to the motion of any body. Oxygen, however, would give greater resistance to motion than hydrogen; but on a little consideration it will be seen that this is not due to its greater density (which, as shown, is not in gases a determining quality of resistance), but rather proportional to it, and this because the density of most gases is inversely proportional to their molecular velocities or receptivity. If, then, with ether we assume an abnormal degree of density, any calculation based on the assumption that its density is proportional to its heating or resisting property will necessarily be erroneous.—Yours, &c., N. G. Thompson.

ETHER, ELECTRICITY, AND PONDERABLE MATTER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In Sir William Thomson's most interesting address he dwelt strongly on the probable existence of some ponderable matter in the ether of space. There must be some kind of structure in the ether, he said, its molecules must have some shape, and they must have some kind of relation to one another; but the difficulties in the way of forming a comprehensive theory are so great that as yet we cannot even imagine a finger-post pointing to a way that can lead us towards the explanation of electro-magnetic phenomena in space.

Might it be possible to erect such a finger-post as Sir W. Thomson believes may be imagined next year, or 10 or 100 years hence, by instituting a parallel between the imponderable, or almost imponderable, ether of the spheres and our better-understood ponderable atmosphere? Pure lifeless air—the unadulterated mixture of nitrogen and oxygen known to the chemist—is non-luminous; it is only when those invisible and impalpable microscopic organisms are contained in it which, within very recent times, have formed the subject of elaborate research by Pasteur, Schwann, Helmholtz and Tyndall, that a ray of light becomes visible during its passage through air.

Such organisms, or germs (which originate fermentation and putrefaction in nitrogenous substances), have been found to be so very slightly ponderable that they require several days to separate themselves from air and to sink to the bottom of an air-tight and quiescent glass vessel 2 feet square; and those who discern in the curiously misunderstood and somewhat discredited Mosaic account of Creation a finger post pointing to the comprehension of how this earth was first rendered habitable for man, explain the Scriptural statement that "in the beginning" the earth was in total darkness, by dwelling on the non-existence of organic matter upon its surface until by or concurrently with the first of the six acts of Creation [*motion* upon the face of the waters] such molecular "germs" were created as rendered the atmosphere penetrable to light from the sun.

Broadly stated, we regard electrical as well as magnetic phenomena as a succession of charges and discharges taking place throughout a series of polarised molecules of matter (liquid or solid), each molecule polarising the next, this the following one, and so on. May we not imagine the ether of space to contain a *something* bearing somewhat the same relation to it and to electricity that those invisible microscopic, or molecular, organisms bear to our atmosphere and to light?—Yours, &c, O. C. D. Ross.

15, Relf-road, East Dulwich, Jan. 19.

[We gravely question whether our correspondent's suggestion will be of much avail in the development of electro-magnetic theory.—ED. *E.*]

THE INSTITUTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Surely the Council of the above Institution have committed a blunder by prohibiting the press reporting Papers, &c. I am afraid this must have a serious effect upon the membership. We in the provinces have always been heavily handicapped, and now we shall know nothing of the Institute's proceedings until months after. Surely the fact of our being debarred from the use of the library unless we visit it (a benefit which is also given to the general public) might have caused the Council to consider carefully before they applied the cloture to the press. We cannot deny there has been a vast amount of gratuitous advertising done at our meetings, but it is well known that the greatest sinners in this respect have at one time or other been members of the Council. Why should there be any difficulty in so arranging matters that our worthy Secretary should with a few strokes of the pen make short work of such advertisements?—Yours, &c.,

A PROVINCIAL MEMBER.

[Our correspondent may like to know that in all probability arrangements will shortly be made for furnishing the technical press with an "authorised abstract" of the discussions. In any case there has been no intention of suppressing the publication of the Papers themselves.—ED. *E.*]

COMPANIES' MEETINGS & REPORTS

The Eastern Telegraph Company (Limited).

The thirty-third half-yearly general meeting of the Eastern Telegraph Company (Limited) was held on Thursday, January 24, 1889, at Winchester House, 50, Old Broad-street, London, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. George Draper) read the notice convening the meeting, and the minutes of the thirty-second half-yearly ordinary general meeting, held on July 19, 1888, and of the extraordinary general meeting, held on the 22nd November, 1888.

The CHAIRMAN having signed the minutes, and the report being taken as read, said: Gentlemen, I shall, as usual, give you some little details, more fully than you have in the report, though the report on the present occasion is very full indeed. Our revenue for the six months ended September, 1888, amounted to £310,104, as against £291,265 in the corresponding period of 1887, showing an increase of £18,839. The chief item of increase is from our holding of shares in the Eastern and South African Telegraph Company, the dividend on which is at the rate of 12 per cent., as against 8 per cent. last year, showing an increase of £7,800. The return for the half-year from our investment in the Black Sea Telegraph Company is increased by £1,393. Our Direct Spanish shares have yielded an additional £307. Interest gives us an extra £600; transfer fees £13; and our general traffic, chiefly South African and South American, £10,531, making a total of £20,644. But we have ceased to bring into our revenue accounts the dividend on Direct Spanish Company's debentures, which are now considered as an investment for our reserve fund; so we must deduct £1,805, leaving the total increase £18,939. The total working expenses for the half year amounted to £83,332, against £79,936, or an increase of £3,396. The details of increase and decrease are as follows:—General expenses in London £7,845, against £8,012, or a decrease of £167; working expenses at stations £59,962, against £56,386, an increase of £3,576. This is principally caused by the number of our foreign staff having been increased to work the triplicate cable from Porthcurnow to Malta and extension to Zante; also the duplexing of same. We have opened a new station at Cadiz, having put that place in telegraphic connection with Villa Real and Gibraltar. The laying of the new cable from Porthcurnow to Malta and Zante, besides giving us greater security and rapidity of working, has diverted to our system a large part of the Greek and Turkish traffic, which formerly went *viâ* the Continent. The foregoing explanations also account in a great measure for the increase in travelling expenses, rent, stationery, and maintenance of instruments. A greater number of messages have been carried this half year than in the corresponding period, and the work to be performed by our staff increases year by year. £1,000 of the total increase in the working expenses is explained by our having carried £5,000 to our reserve fund for the maintenance of ships, against £4,000 last half year. Repairs to cables amounted to £43,075 against £34,102, or an increase of £8,973. This is always an uncertain item in our accounts. Our ships have been busily employed in maintaining our system in a state of efficiency. The increase under this head is in the value of the new cable laid in, the total length being 130 miles, against 38 miles in the corresponding period of 1887. You will find on reference to the reserve fund that we have applied over £13,000 in reduction of capital expenditure, or, in other words, although we have spent over £13,000 in extending and improving our system, the capital expenditure remains at practically the same figure as last time. The Six per Cent. Debentures of the Direct Spanish Telegraph Company have been transferred to our reserve fund investments, which stand at £315,494, and our total reserves, after deductions, at £355,676. We pay the usual interim dividend at the rate of 5 per cent. per annum, and after providing for interest on Debentures, Debenture stock, and Preference shares, we are able to carry £36,616 forward to our next account, against £29,397, or £7,219 more than in the corresponding period of 1887. Now, gentlemen, I have given you these details because I think it desirable that you should follow as closely as possible the practical action of the Company. The statement I made in November last was so full of detail, so complete a history of the Company from the beginning, that it leaves me comparatively little to say to you to-day excepting this, that all that we put before you at the last meeting has been carried out. All the shares have been allotted and fully taken up; the work is in hand, and I believe by the time I have the pleasure of meeting you six months hence, if I have that pleasure, we shall have completed our West Coast of Africa cable; and that will not be completed one hour too soon. The enormous traffic going on just now to the Cape and the Transvaal, caused by the gold speculation, of course brings a great deal of grist to our mill. Any interruption to the present cable would be very disastrous, and would be felt to such a degree in London that I almost fear to contemplate what the outcry would be. When we have this cable completed we shall have two strings to our bow, and we shall thus meet, I fully believe, all the telegraphic requirements of the public. I may say that our system is working thoroughly well. We have a great deal of work to do to ensure that. I mentioned the very large sum we spent for repairs, but I think it is just worth while to give you some idea of the labour that is going on and the way our ships are employed. I think the information will be interesting to you. The work is so silently done that the public do not know anything about it. What we do shows that in our cable system we have a solid property. We are maintaining for the public benefit a grand system of cable communications, and it is done at considerable expense and a considerable amount of labour, our ships, I may say, being almost constantly employed on the work. As I said, the public do not know this, but we know very much about the details of the thing, and every day gives me more confidence in the working of our system. At the same time I am bound to tell you that cables, as well as men, get old, and we have to take care that we have all the older cables replaced by new ones; and we are trying to effect that out of income rather than by increasing the capital of the Company. The information I am now about to give you respecting the repairs applies to the last six months. On the 11th of August the Perim-Suakim cable was repaired; on the 9th of September the Aden-Bombay No. 1 cable was repaired; on the 19th September we repaired the Aden-Suez cable; on the 26th September the Perim-Suakim cable was again repaired, and again on the 10th of December. I think you may have observed in the papers that our ships, being in the neighbourhood of Suakim, gave every possible assistance to the British Government while the Egyptian and English troops were in action at that particular place. We have many times received thanks for the way we have acted in assisting them. We have taken away their wounded, and in great emergency have conveyed soldiers. I must say that our services have been thoroughly appreciated. I only hope, when we come to make a bargain with them, they will bear this in mind. The repairs I have already mentioned were done by one vessel. The repairs by another vessel were as follows:—On the 31st of August the Malta-Alexandra No. 1 cable; September 25, the Patras-Corinth cable; October 3, the Zanto-Corfu cable; October 9, the Rhodes-Sitia cable; November 19, the Chios-Tenedos cable; November 23, the Alexandria-Malta No. I cable; on November 27, the Suez-Suakim cable.

Digitized by Google

Then there were the repairs by the "Electra" to the Aden-Bombay No. 2 cable, the Porthcurnow-Lisbon No. 1 cable, the Vigo-Lisbon cable, and the Vigo-Lisbon cable again. The "Amber" repaired the West African Company's Bolamo-Bissao cable (which we look after), the African Direct Company's Accra-Lagos section and the Lagos-Brass section, the Lipari-Milazzo cable, the Port Said-Alexandria cable, and the Thermia-Zea cable. During the six months we have had in all twenty-four repairs, and to effect those repairs our ships have had to steam 25,000 miles. That gives you some idea of the work that is going on every day; but at the same time, as you know, we have maintained our system in a thoroughly efficient working state, so far as the public are concerned. What I have stated, however, shows you the necessity of duplexing and duplicating the system. Had we not duplicated the system, and applied the duplex, we could not possibly have carried out the work we have done. I have frequently stated to you that above all things we desire to maintain the efficiency of our cables. We know that if we do that the public will get confidence in us, and then there can be no doubt of our having a growing and prosperous concern. The world cannot live now without the telegraph, and it is our duty, knowing the whole of the working as we do, to take care—without unduly increasing the capital, and while paying the shareholders a fair dividend—to maintain such a state of efficiency as will secure the confidence of the telegraphing public, and the confidence of the great body of our shareholders, which we value so very much. I now beg to move—

"That the report and accounts of the Directors to the 30th of September, 1888, submitted to this meeting, be, and the same are hereby, received and adopted."

The MARQUIS OF TWEEDDALE: I beg to second that.

The CHAIRMAN: If any gentleman is desirous of making any remark or putting any question, I shall be very happy to reply. Those in favour of the motion please hold up their hands. To the contrary. Carried unanimously.

Captain GOODSALL: Can you inform the shareholders how far from Aden or Bombay the No. 1 Bombay cable has gone?

The CHAIRMAN: I expected to have a report in to-day that the repairs had been effected. We expect every hour to hear that the cable is spliced.

Captain GOODSALL: What is the distance?

The CHAIRMAN: Seven hundred miles from Aden.

Captain GOODSALL: Has the cable been repaired there before?

The CHAIRMAN: Not at that particular place.

Captain GOODSALL: What is the condition of the cable?

The CHAIRMAN: You are an old servant of the Company?

Captain GOODSALL: I am.

The CHAIRMAN: You should know all these points as well as we do.

Captain GOODSALL: The shareholders may wish to know as well as I do.

The CHAIRMAN: The gentleman now addressing you was a captain in the Company's service. I may say that he left the service for the good of the service, and therefore I have nothing further to say. In putting his questions he has some object; but if he wants any actual information as a shareholder, he is perfectly entitled to it.

Captain GOODSALL: I am asking for information for my own use, and the use of the shareholders. I want them to know about the matter as well as I do. You have an account for advertising—kindly tell me where you advertise in London. I have only seen an advertisement in *The Electrician*, and if we pay £221 for that we are paying too much. Last half-year it was £540. It is not right for the Chairman of the Company and the Managing Director to have a share in a paper—that is, in the only paper that the Company has advertised in. Why not advertise in the *Electrical Review*? No, because your Chairman and Managing-Director advertise in a paper which is their own property. We ought not to advertise in this paper. Advertise in *The Times*, if necessary, where there are 50,000 or 60,000 copies a day. *The Electrician* has probably about 2,000 a week. Here is another thing, £1,034 for office expenses. I have looked over several companies' accounts and I find that many of them get on very well without office expenses. Here is another point. The "Mirror," £8,800 for working expenses. This is far too much from what I know of the work. From that I can gather that the Chairman was away with a number of friends cruising.

The CHAIRMAN: Hear, hear.

Captain GOODSALL: But you ought to pay that portion, and not charge the Company with it. That is the proper way. I leave this to the shareholders. They can hear what you say about me, that I am a discharged servant.

Dr. WALLER: I am glad to hear the gentleman conclude by saying he will leave these matters to the shareholders. In my judgment (and I have attended as many meetings as most men) I never saw anything so irregular, so disorderly as this gentleman's proceedings to-day. He has appealed to the shareholders. I do not hear one sympathetic voice in approval of the course which this discharged captain has taken to-day. I am very glad to hear by the acclamations that my view and not his is the view of this meeting. Sir John, I hope you will not condescend to any further explanation in the matter. We can all pretty well understand it. I shall therefore myself leave the matter, having risen—merely because there was an appeal to the shareholders—to express my feelings, which I am glad to see are the feelings of the shareholders present.

The CHAIRMAN: I would have treated—and I do treat—the remarks of the gentleman (Captain Goodsall) in the way they ought to be treated, but there are two points I must deal with. It does appear to the shareholders as if there was a charge against the Company. First of all, I would reply to what has been said in connection with *The Electrician*. I want gentlemen connected with our Company to know that *The Electrician* was established for the purpose of recording the best scientific opinions upon questions relating to telegraphy and electricity. Sir James Anderson, myself, and one or two other gentlemen interested in telegraphy, established that paper, but we have never taken a shilling profit out of it since it was established. We have established it mainly for the benefit of the great system with which we are so closely connected. It is an enormous benefit to our *employés* to be kept informed of the scientific progress of the business in which they are engaged. I think that is a sufficient answer. It is very important that telegraphic science should be disseminated among those in our service, so as to make our work more and more progressive and satisfactory. As to the other point - and I say this with all due deference—I do go about occasionally in the autumn and sometimes in the spring when there is any important negotiation going on. These negotiations I have found much more successful when carried out by interview than when conducted by correspondence. I can say with the greatest confidence—and I am a large shareholder—that the Company would not have occupied the position it does to-day but for our coming into frequent intercourse with the Great Powers of Europe. I have taken advantage of the ships occasionally when they have been moving about from place to place for the purpose of cable repairs, and I have taken friends with me—gentlemen of distinction whose opinion is of the greatest importance and value, and cannot fail to be of benefit to us. These occasional visits which some of the Directors, Sir James Anderson, and myself, have made from time to time, have added strength to our position; and we intend to continue them, as we believe they are in the interest of the Company. There is a very important business now pending—the renewal of concessions in a certain part of the world. It is no advantage to me—but rather the contrary to go; but I am going abroad in connection with the business because I think I shall do good in bringing about a renewal of these concessions on such terms as will be satisfactory and beneficial to the Company. I thank you for listening to these personal explanations. It is a pity that they should be required at all, but I have made them, and I hope they will be satisfactory. The motion has been seconded, and I now put it to the meeting. To the contrary. Carried unanimously.

Mr. BURNEY: Were the debentures offered at the extraordinary general meeting all taken up?

The CHAIRMAN: Yes, everything is placed. The next resolution is—

"That Lord Sackville A. Cecil, who now retires, be, and he is hereby re-elected a Director of the Company."

Sir JAMES ANDERSON: I beg to second that.

The CHAIRMAN put the motion in the usual manner, and declared it carried unanimously.

Lord SACKVILLE CECIL: Gentlemen, I am very much obliged to you for this renewal of your confidence in me.

The CHAIRMAN: The next resolution is—

"That Sir Albert J. Leppoc Cappel, who now retires, be, and he is hereby, re-elected a Director of the Company."

I think I should state to you who Sir Albert Cappel is. He has been at the head of the Telegraph Department in India for a considerable number of years. He is thoroughly acquainted with telegraphic work in India, and we thought it would be a very great advantage to have a gentleman of his experience on the Board. It keeps us in touch with the Indian Government, and my opinion and the opinion of the Directors is that it will prove a great benefit to the Company. We made this selection purely on the ground that Sir Albert Cappel was the best man we could find to fill the seat at the Board rendered vacant by the death of Lord Alfred Paget. I can only assure you, from my own observation and from the correspondence that passed between India and London while Sir Albert Cappel was at the head of the department there, that he is one of those men who have taken a deep and earnest interest in the progress of telegraphy.

Mr. G. G. NICOL: I have great pleasure in seconding the motion.

The CHAIRMAN put it in the usual way and declared it carried unanimously.

Sir A. J. L. CAPPEL: I am exceedingly obliged to you for re-electing me on this occasion. I hope to do all that is possible to justify your confidence hereafter.

Dr. WALLER: Sir John Pender, I beg to move

"That Mr. Henry Dever and Messrs. Welton, Jones and Co. (formerly Messrs. Quilter, Welton and Co.), both of whom now retire, be, and they are hereby, re-elected auditors of the Company for the current year at a remuneration of £100 each."

In proposing this resolution I will take permission, being on my legs, just to make these observations—that very often out of evil comes good, and that the shareholders are very much indebted to you for some of the statements you were good enough to make in regard to your action as Chairman; and we all think that your journeyings about, however inconvenient to yourself, are vastly remunerative to the Company. You made use of a very true expression at the beginning of the meeting. You said that cables, like men, grow old. I do not know much about cables, but I ought to know something about men, considering the length of time I have mixed with them I know of only one exception to the statement about men growing old, and that exception is our honoured Chairman, who, in my opinion, is labouring under the "chronic disease" of vigorous prime. Long may he continue to do so, and to give that service to the Company which has made it the greatest telegraph company in the world.

Mr. FOX: In seconding the proposal which this gentleman has moved, I also support very warmly the way he has spoken of our Chairman. I feel that the Company is very much indebted to the Chairman for what he has done in advancing our interests. I only hope it will not be very long before he will be able to advance our interests in the House of Commons, as he did before.

The CHAIRMAN: I will read the resolution. Having read it, he put it to the meeting, and declared it carried unanimously. Addressing Mr. Burney, he added: I made a mistake just now in replying to your

Digitized by Google

question. What I meant to say was that all the shares were taken. The debentures are not all issued, and we are not dealing with them yet.

Mr. BURNEY: I think you offered them to the shareholders at the last extraordinary meeting.

The CHAIRMAN: There is a portion still to be issued. There are also the South African Company's debentures. We do not want the money, and are not pressing the issue; but if any shareholder will apply at the office we will give him any information he wants on this matter.

Mr. BURNEY: I see that the Five per Cent. Debentures stand at 103, 104, and I was wondering how the Four per Cent. Debentures would be taken up at par.

The CHAIRMAN: I have not the least doubt that when we want the money we shall get it at par. As you are aware our Eastern Four per Cent. Debentures stand high in the market.

Mr. BURNEY: Yes, I am aware of that.

The CHAIRMAN: Well, while it is not a guarantee, so long as there is a shilling in the exchequer of the Eastern Company I do not think these debentures will suffer That is all our business.

Mr. BURNEY: I beg to move that we pass a vote of thanks to the Chairman for his able conduct in the chair to-day.

The CHAIRMAN: I thought, from the complimentary way in which Dr. Waller spoke he had for the moment moved that vote of thanks.

Dr. WALLER: I should have have done it, but I did not like to speak too much.

The CHAIRMAN: It was a very warm expression of opinion indeed, which I feel very much, coming from you and the seconder, and on behalf of my colleagues and myself I desire to say that we greatly appreciate the confidence you continue to give us. I am sure that the greater the confidence that exists between that side of the table and ours the better for the interests of the Company. We have never hidden anything from you; we have given you every opportunity of judging of questions on their merits, and we shall continue to do that as long as we conduct the affairs of the Company. I thank you very much.

The proceedings then terminated.

The Direct United States Cable Company (Limited).

The twenty-third ordinary general meeting of this Company was held at Winchester House, 50, Old Broad-street, on the 25th ult., Sir John Pender, K.C.M.G., presiding.

The SECRETARY (Mr. T. Finnis) read the notice convening the meeting and the minutes of the last ordinary general meeting, which were confirmed by the present meeting and signed by the Chairman as correctly entered.

The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN then said: As usual, gentlemen, I will give you some details, in addition to those mentioned in the report in your hands—a report which is rather full than otherwise. The revenue for the half-year to December 31st, after deducting out-payments, amounted to £34,188. The working and other expenses, including income-tax, but exclusive of cost of repairs, were £16,476, leaving a balance of £17,712 as the net profit of the half year. Adding to this balance the sum of £6,071, transferred from the reserve fund account for dividend purposes to 30th June (that is, to the end of our last financial year), the total becomes £23,783, which has been appropriated as follows:—Final dividend of 2s. per share for the quarter ended 30th June, 1888, £6,071; interim dividend of 2s. per share for the quarter ended 30th September, 1888, £6,071; together £12,142, leaving a balance of £11,641 on the revenue account. A further interim dividend of 3s. 6d. per share for the quarter ended 31st December last, being at the rate of 3½ per cent. per annum, has been declared, and the dividend warrants will be posted this evening. This will require £10,624, leaving a balance of £1,017 to carry forward. The revenue for the half year (which included only four months at the 1s. rate, the 6d. tariff having been in force up to the end of August) shows an increase of £11,185 over that of the corresponding period of 1887; but no reliable comparison is afforded by these figures, because the 6d. tariff was in force throughout the whole of the six months to December, 1887. The 1s. tariff, however, has brought about some reduction in the volume of the traffic, as was naturally to be expected, but the earnings so far have been fairly augmented. The expenses in London, compared with the corresponding period, show as follows:—A reduction of £249 in salaries, increase of £107 in printing and stationery, £40 in office expenses, and £14 in stamps, these increases being wholly chargeable to the alteration of the tariff, which has involved the preparation and issue to nearly all parts of the globe of a very large number of tariffs and other notifications. The expenditure at the stations, including, of course, the additional new station at Boston, compares as follows:—A reduction of £294 in salaries and of £115 in printing and stationery. An increase of £399 in maintenance is due chiefly to some rather extensive repairs to instruments which had to be sent from Nova Scotia to London for repair, and which should not require further outlay on them for some time. Travelling expenses stand at £132 increase, through necessary transfers of operators at stations, which did not take place in the corresponding period of 1887. The increase of £243 in repairs and renewals to buildings, &c., is accounted for chiefly by extra repairs made during last summer to the buildings forming the Company's Ballinskelligs station. The remaining stations' expenses are practically unaltered. In the other expenses, directors' fees are reduced by £157, but the item of "use of patents" increased by £196, payment of royalty having had to be made while the cable was under repair. £233 has been written off for depreciation of spare cable and cable tank, and £271 stands for cost of storage and insurance of spare cable. These two items did not appear in the expenses of the corresponding period. This fact, and the special outlay for repairs above referred to will more than account for the difference of £610 in the expenditure as a whole, as compared with December, 1887, when the expenses were reduced to a minimum. The reserve fund account, after being credited with the interest on the investments and profit on securities realised, and being debited with the outlay on the removal to Halifax and the cost of deep sea repairs, now stands at £239,206. The special expenditure on the removal and the deep sea repairs ought to be recouped to the reserve fund as soon as convenient. The investments continue, as heretofore, to be worth considerably more than they are stated at in the balance-sheet. We have given you very full details of the expenses and the ups and downs that have taken place in the past half-year, and I will now proceed to make a few remarks upon our position since I last had the pleasure of addressing you. We were then in the midst of a most important repair. We had secured one end of the cable, and that was at a depth of over 2,000 fathoms. We then had very bad weather indeed in the Atlantic; but notwithstanding the bad weather—of course it prolonged the operation—we picked up the other end of the cable, and we have now got what I may call a very perfect cable indeed. During the last day or two we have resumed duplex working, and our power is now almost double what it was in the past three or four years. That is fortunate in many respects, and it places us in a position to take a very important part in the work which is being now operated. When I last addressed you we were also in the midst of another business—that was the settlement of the tariff—whether it was to be 1s., or what it was to be. I think the opinion was very strong indeed on the part of the Anglo Company and this Company that we should go to 1s. So far we have not been disappointed in the 1s. tariff; but I may tell you that we do not get as much money as we ought to get out of the 1s. tariff to pay a fair dividend. However, we are getting about double the money we were getting during the last four months of the 6d. rate, and I am hopeful, when people get accustomed a little more to the extra 6d., that the traffic will go on increasing. The commerce of the world, as you know, is now conducted more or less by submarine telegraphy—that is to distant places—and the growth of the traffic must continue if the country grows. We already see a very marked growth, and it is very important to have established the fact that we receive from the 1s. tariff nearly the same amount of traffic that we had under the 6d. tariff. We are giving the telegraphing public a fair trial of a very cheap rate, and I hope that no alteration in the future will be necessary. In regard to our cable, I think we have every reason to be proud of the way in which the Direct Cable Company has stood its own during all this time. Another cable company—a single cable company—the French Company, is in a very different position to what we are in. We stand with a good reserve fund, with a renewed cable, probably as good for our purpose as the day upon which it was laid. We have put in a considerable amount of new cable in the deep water portion, and I think we are probably standing in as good a condition as any cable company can stand. We have effected considerable changes, which are noticed in the report. We have reconstructed the working of our Company, and have, I think, put it in a position quite as efficient as any existing cable company. We have taken away our office from Chester to Liverpool, but having re-established the duplex system upon our cable, we have, in connection with that duplex system, recognised the people who were working at Chester. The reconstruction has effected a considerable saving. We have also placed the management of the Company in a position which has effected another saving of at least £1,200; and I repeat that, looking to the management of the Company from first to last during all this period of hard times, I think we have come before you to-day showing that we are now, I hope, making a fresh departure, with our cable restored, and with a fair and moderate tariff, and we are able to take our part in this work quite as well as any of the other cable companies. With these remarks I beg to move the following resolution:—

"That the report of the Directors dated 11th January, 1889, together with the statement of accounts to the 31st December, 1888, annexed thereto, be, and the same are hereby, received and adopted."

Mr. WILLIAM FORD seconded the motion.

Mr. JACKSON thought that the results of the 1s. tariff so far should be eminently satisfactory to the shareholders. There must be in all their minds a conviction that their position was growing better. The Chairman had not mentioned a circumstance that it was very important for the shareholders to know. In the report of the Anglo-American Company they were informed that there was something like an agreement between the "pooling" companies for 12 months. That was a stroke of policy upon which the Board should be congratulated, as well as upon the present position of the Company. He thought that the contracts for repairs should always be open to tender from the large companies. He wanted to point out the extraordinary fact that the Direct Cable repairs for the last year cost £58,000, whereas those of the Anglo-American Company—and he thought that company had far more breakages—were represented by £21,000. The Anglo-American Company possessed certain advantages over the Direct Company for repairs, but still the figures showed so great a difference that he hoped this would be the last time that any contracts would be given to any company unless by tender.

Mr. GUESDON said he had always been an advocate for cheap tariffs, believing that low prices in every thing increased consumption. High profits always tempted competition, and hence three cables had been established since the Direct Company was secured by the Chairman. He agreed with the previous speaker that they ought always to invite tenders for cable repairs.

The CHAIRMAN: I will reply to the honourable shareholders. Mr. Jackson is an old stager. He has just told us he has been connected with the Company from the very beginning. As he occasionally pays a visit to the office, I think he ought to be rather better informed than he is to-day. I will take the last part of his statement first. He ought to have been aware that we did invite tenders for the repair of the cables. We

Digitized by Google

had tenders from three of the very first companies, and we submitted those tenders to an eminent firm of consulting engineers, and they reported as to the tender we ought to accept, and that was the tender we did accept. One of the tenderers came to me afterwards and said (for I explained the whole matter to him), "I think you are perfectly right in having accepted that tender; they were people who could do it better and cheaper from their knowledge than any of the other parties." That I think most satisfactory. You cannot, therefore, teach us what we ought to do. We have done a very great deal indeed for the Direct Company. When it came into our hands it had been four years in existence. It had a debt of £100,000 hanging over it, which was very likely to strangle it. It was going down every day, and when we stepped forward to rescue it, we rescued it when it was all but wrecked. We brought it into condition almost immediately. We have from the first time we took charge of it up to the late reduction of rates, when the strong competition began, paid our shareholders 5 per cent. upon the £20 shares, and we have put aside a quarter of a million of reserve fund. If that is not good management, I do not know what good management is. As to its being an unfortunate company, I admit that in the first stages it was very unfortunate—unfortunate in its cable, unfortunate in working it; in fact, it was a series of misfortunes and unfortunately nearly every shilling of the original capital was lost. We did save some of it, however. When we took possession of the Company its shares were £4 or £5. They are now about £10, and when we compare ourselves with the French Company and see their £20 shares at £4, ours being as I said at £10, I put it to any fair-minded man whether our position has not very much improved. I put that to the gentleman more particularly who addressed us on this subject. He used to give us credit, but he gives us no credit now. However, he has got some idea that I am overstraining and overworking myself; but depend upon it there is no want of vitality, in any shape or form, either on the part of myself or any member of the Board, in conducting the affairs of the Company in a thoroughly efficient way, and it will compare with any existing submarine cable company. I think that that is a sufficient answer, and I think my friend will accept that.

Mr. JACKSON said he did not go into the ancient history of the Company. What he remarked was that whereas the repairs of the Anglo-American Company, for a larger number of breakages, cost £21,000, those of the Direct Company cost nearly £60,000, and he thought that some explanation was due to the shareholders as to the difference. He contended that they were entitled to investigate that unsatisfactory feature of their affairs.

The CHAIRMAN: I am very much astonished at the hon. gentleman's statement. If the question were put to Mr. Weaver now he would tell you that they have spent in the Anglo Company on a single repair in the Atlantic over £80,000. Over £80,000 has also been spent in repairing the French cable at different times. You are comparing a great and important repair—perhaps the most important repair ever made in a submarine cable—with ordinary repairs of cables in the Atlantic. There is no comparison.

Mr. JACKSON: There is some comparison. The repair of the Brest cable was a more difficult matter.

The CHAIRMAN: I am rather surprised at my friend, whom I have recognised as rather an authority in submarine cable matters. His want of knowledge to-day shows me that he has not been giving the attention to these matters that he used to do when in business. I think I have answered to the satisfaction of the shareholders the questions put to me. He then put the motion in the usual way, and it was carried unanimously.

On the motion of Mr. JACKSON, seconded by Mr. JOHN VARLEY, a vote of thanks was unanimously accorded to the Chairman and Directors.

The CHAIRMAN, in reply, said: I am very much obliged to you for the way that my name has been received, and I thank you on behalf of myself and my colleagues. We are here to do our duty to the shareholders and to the telegraphing public generally. As long as we do that we are satisfied that men who look at these things from a fair and just point of view will not refuse to accord us what is our due.

The proceedings then terminated.

Metropolitan Electric Supply Company (Limited).

An extraordinary general meeting of the members of this Company was held at the offices, Winchester House, Old Broad-street, on the 25th ult., Sir John Pender, K.C.M.G., in the chair, for the purpose of confirming the resolution of the extraordinary general meeting, held on the 8th ult., altering Clauses 26, 45, 102, 119, 121, 123, 130, and 155 of the Articles of Association of the Company, as published in *The Electrician* on Jan. 11th.

The SECRETARY (Mr. E. Cunliffe Owen) read the notice convening the meeting.

The CHAIRMAN: Gentlemen, you have heard the resolution read, and this meeting is called for the purpose of confirming it. He then moved the confirmation of the resolution.

Mr. J. C. PARKINSON seconded the motion.

The CHAIRMAN put it in the usual way, and having declared it carried, added: We are going on with our installations as quickly as we possibly can. We have now one station at work, and two others are in course of construction, and we expect that they will be ready by April. Mr. Gordon tells me that we have settled the contract with the Grand Hotel and the Hôtel Métropole to supply them from the existing station at Whitehall. My impression is that we shall have more demands upon us than we shall be quite able to supply for some considerable time. However, if energy will meet the whole of the requirements there will be no want of that.

Anglo-American Telegraph Company (Limited).

Report of the Directors to the ordinary general half-yearly meeting of the proprietors, to be held at Winchester House, Old Broad-street, London, E.C., this day (Friday) at two o'clock:—

1. The total receipts from the 1st July to the 31st December, 1888, including the estimated balance of £390. 12s. 8d. brought forward from the last account, are estimated at £131,186. 6s. 11d. This amount is, however, subject to revision upon settlement of the accounts with the Paris-New York Telegraph Company. The traffic receipts show an increase of £35,352, as compared with the corresponding period of last year.

2. The total expenses of the half year, including repair of cables, &c., as shown by the revenue account, amount to £51,110. 13s. 11d.

3. Interim dividends of 7s. 6d. per cent. on the Ordinary stock, and 15s. per cent. on the Preferred stock, were paid on the 1st November last, absorbing £25,250, leaving an estimated balance of £53,825. 13s., out of which the Directors recommend the proprietors to declare final dividends of 15s. per cent. on the Ordinary stock, and £1. 10s. per cent. on the Preferred stock, amounting to £52,500, making a total distribution for the year ended the 31st December, 1888, of £1. 12s. 6d. per cent. on the Ordinary stock, and £3. 5s. per cent. on the Preferred stock, leaving an estimated balance of £1,325. 13s. to be carried forward to the next account.

4. The Company's repairing ss. "Minia" has been engaged during the past half year in the repairs of the Brest-St. Pierre cable, the St. Pierre-Duxbury cable, the Southern Placentia-Sydney cable, the tricore Placentia St. Pierre-Sydney cable, the Prince Edward Island cable, and the shore end of the 1873 cable at Heart's Content. The Brest-St. Pierre cable was broken in four places, two of the faults were in deep water, and two in shallow water. The total cost of the repairs to the Brest-St. Pierre cable amounts to £21,924. 15s. 3d., all of which has been charged to the renewal fund, a large quantity of cable having been expended in the renewal of the line. The interruptions to which the St. Pierre-Duxbury cable has constantly been subjected by the anchors of fishing vessels have decided the Directors to divert and renew a considerable length of the line during the course of the approaching season. The cost of this work will also be chaged to renewal fund.

Digitized by Google

5 The Company's system of cables and land lines is in good working order, with the exception of the North Placentia-Sydney cable and Island Cove cable, both broken within the last few weeks.

6. The litigation between the Anglo-American Telegraph Company and the Paris and New York Telegraph Company is still pending, the points referred by the Paris Court of Appeal to the Conseil de Prefecture de la Seine for interpretation not having yet been heard.

7. A memorandum of agreement was entered into on the 30th July, 1888, between the Anglo-American Telegraph Company (Limited), the Direct United States Cable Company (Limited), the Western Union Telegraph Company, La Compagnie Française du Télégraphe de Paris à New York, the Commercial Cable Company, and the Postal Telegraph Cable Company, by which the tariff for messages between Europe and New York and Canada was increased from 6d. to 1s. per word, and to 5d. per word for Press messages. The new tariff came into force on the 1st September last, and is to continue for one year certain, thirty days' notice by either of the parties being necessary to determine the same.

8. It is not possible to say after so short an experience whether the 1s. rate will ultimately become a financial success, but so far the results may be considered as fairly satisfactory. The first four months of the 1s. rate, as compared with the last four months of the 6d. rate, show an increase of 111 per cent. in the revenue, and a decrease only of 11 per cent. in the volume of traffic. As compared with the corresponding four months in 1887, an increase of 77 per cent. is shown in the revenue, and a decrease of 26 per cent. in the volume of traffic carried. The differences between the several periods compared are largely due to the normal variation of traffic during the months under consideration, and to the proportionate alterations of percentage in the amounts paid out to connecting companies, under the 6d. and 1s. rates respectively.

9. In accordance with the Articles of Association, two Directors of the Company, Sir James Anderson and Mr. William S. Cunard, retire at this meeting, and, being eligible, offer themselves for re-election.

10. Mr. Joshua Dean and Mr. Francis Glass, the auditors, also retire, and offer themselves for re-election.

Cuba Submarine Telegraph Company (Limited).

Report of the Directors for the half year ended 31st December, 1888, to be presented at the thirty-fifth ordinary general meeting of shareholders, to be held on Wednesday, the 6th February, at one o'clock.

2. From these it will be seen that the gross receipts (including the balance brought from last account) amount to £21,904. 12s. 10d., and the gross expenditure (including the half of the annual payment on account of the 1881 cable) to £6,395. 16s. 11d., leaving a sum of £15,508. 15s. 11d. to the credit of revenue account.

3. Of this the sum of £4,000 has been added to the reserve fund, increasing that fund to £84,000.

4. The dividend on the Preference shares will absorb £3,000, and leave £8,508. 15s. 11d., out of which the Directors recommend the payment of a dividend on the Ordinary shares at the rate of 9 per cent. per annum, free of income-tax, the balance, £1,308. 15s. 11d., being carried forward to the current half-year's account.

5. The cables have continued in good working order throughout the half-year, although the Cienfuegos-Batabano section is showing signs that some repairs may shortly have to be made upon it.

Taunton Electric Lighting Company (Limited).

Report of the Directors to be presented at the second annual general meeting of the Company, to be held at the Castle Hotel, Taunton, on Monday, February 4th, at six o'clock p.m. :—

The number of shares allotted is 954, on which the sum of £4,750 has been received. The accounts for the year show a profit of £355. 18s. 3d. Your Directors recommend that a dividend of six per cent. be paid, free of income-tax. This will take £272. 0s. 5d. The balance carried on for a reserve and depreciation account, including the amount from 1887, will be £207. 13s. 9d. In addition to the Taunton business, the Company has carried out temporary installations in Bristol, Bath and Exeter.

Deputations from various places have visited Taunton during the past year for the purpose of inspecting the Company's works and the lighting arrangements of the town, the general testimony being that it is the most successful installation in central station lighting yet carried out in the United Kingdom. The machinery has been maintained in excellent working order, those portions of it which are continuously wearing out being made good and charged to income account. The present engines are rather extravagant in their consumption of fuel : your Directors therefore recommend that as the demand for private lighting is rapidly increasing, engines of the highest possible efficiency should now be put down, using the present engines as duplicate plant only. This will effect a saving of nearly £200 per annum in coal, water and oil. It is desirable, also, to largely increase the electrical plant, to enable your Directors to cope with the increasing business, and they therefore propose to offer at par the remaining share capital of the Company.

Should the applications for shares exceed the number offered, the present shareholders will receive priority of allotment in proportion to the number of shares they now hold. A form of application for shares is issued with the balance-sheet. Three of the Directors retire by rotation, and are eligible for re-election, namely, Messrs. Bale, Withycombe, and Potter. The auditor, Mr. Albert Goodman, retires, but is eligible for re-election, and offers himself accordingly.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended January 25th amounted to £5,435.

EASTERN TELEGRAPH COMPANY (LIMITED).—Notice is given that the share certificates for the New Ordinary Shares will be ready for delivery, in exchange for banker's receipts, on and after the 4th February next.

NATIONAL TELEPHONE COMPANY (LIMITED).—The accounts of this company made up to December 31, show a gross revenue of £117,726, as compared with £99,563, and the directors have declared a dividend for the six months ended December 31st last at the rate of 6 per cent. per annum on the First and Second Preference shares, and an interim dividend at the rate of 4 per cent. per annum (being at the same rate as for the corresponding period) on the Ordinary shares, carrying forward £10,399, of which £3,500 is set aside against an outsanding claim. The unaccrued revenue carried forward amounts to £54,385, as against £45,826, at the same period of the previous year.

THE DIRECT SPANISH TELEGRAPH COMPANY inform us that direct cable communication with Spain is restored.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this company for the week ended January 25, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,550.

THE CYCLOSTYLE

Price from 21s. Gestetner's Patent.

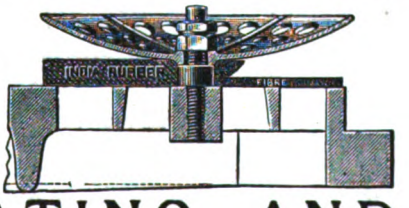
This is the best apparatus ever invented for taking a large number of copies from *one* original writing or drawing. It offers many advantages over any other system. In the first place, the writing with it is as easy and as quick as with an ordinary pencil. The process of writing can be suspended and resumed, if circumstances require it, without any difference whatever, at any subsequent time. Anybody can do the *printing* part of the arrangement—a lad or boy. The resulting copies, which can be obtained in any desired number, it only being a question of time, are in a *permanent* ink, no matter what the colour, and can, therefore, be put away and filed for reference years afterwards. There is no washing, no **soaking**, no melting, and no copying press necessary, nor is any recourse had to electricity or chemicals. In use at **Lloyd's** and many of the principal **Shipping** and **Mercantile Houses, Colonial Brokers, Solicitors,** &c., in the City.

Send for Specimens of work done and Price Lists to the Chief London Depôt :

FACSIMILE APPARATUS CO., 79a, Gracechurch St., London, E.C.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 560.—Vol. XXII. FRIDAY, FEBRUARY 8, 1889. Price Fourpence.

NOTES.

The Committee of the Electrical Trades Section of the L.C.C., at their meeting on Monday last, had under consideration the very important question of the possibility of inducing manufacturers of electrical apparatus of all kinds to conform, so far as possible in the matter of voltages, gauges, &c., to certain standard types. The great advantage—both to the trade and to the public—which would follow from the general adoption of such standards is so evident that there can be no need to insist upon it here. The prevailing system, or rather want of system, is a continual source of worry and expense to every one concerned. Take the case of voltages alone—we believe we are correct in stating that the Edison-Swan Company has manufactured lamps to order during the last twelve months of *over one hundred* different voltages. It is surely impossible to believe that any sound reason exists, either scientific or economical, which can cause a demand for such a multiplicity of types. The same thing applies with perhaps even greater force to dynamos. It is an understood thing that if manufacturers could settle down to a limited number of types the profits of the trade would be immensely increased. As it is, they are constantly engaged in designing and building special machines to meet the requirements of specifications which are often drawn up apparently without either rhyme or reason.

But although there is no room for dispute as to the existence of the evil, it is quite another thing to find an efficient remedy. The question is one of the greatest difficulty and of no little delicacy; and this is fully recognised by the Committee. If there is one thing more certain than another to annoy an Englishman it is for anyone else to suggest to him how he should manage his own affairs, and the Committee are most anxious that it should be clearly understood that they have not the slightest intention of taking any action which could be so construed. On the contrary, all that has been done so far is to nominate a widely representative Special Committee — consisting of a large number of manufacturers and contractors—who are merely requested, in the first instance, to consider whether it is advisable to attempt anything of the kind indicated, and if so, how best to proceed. Several members of the General Committee, whilst recognising the great advantages to be gained, expressed a fear lest the provincial manufacturers, and particularly those who do not happen to be members of the Chamber, might feel that their interests had been ignored. To avoid any such feeling it should be clearly understood that the Section is anxious to listen to the views of everyone concerned, and in any case nothing will be done in a hurry, nor without the fullest consideration. It is, in fact, evident from the nature of this question, that nothing effectual *can* be done unless a practical unanimity is arrived at. For our own part we are convinced that the effort is worth making, and although we do not conceal from ourselves the extreme difficulties with which the question is beset, still in view of the markedly conciliatory and sensible tone in which it has been taken up, we by no means despair of a solution.

The local authorities of no less than four important districts have issued reports on electric lighting within the last few days. The City report and that of the Kensington Vestry (both of which we print on another page) are on the whole very favourable to the immediate prospects of electric lighting in the metropolis. On the Kensington report we have something to say in our leader. Abstracts of the Brighton and Birmingham reports will be found in the Notes; they are both of an unfavourable character.

In view of the somewhat disappointing character of the discussion which followed the reading of Prof. Jamieson's Paper on "Insulation Resistance in Installations," it would seem almost a pity that the Institution of Electrical Engineers is to devote another night to the same subject. As a matter of fact, we are inclined to think that Prof. Jamieson has already said all that *can* be usefully said on the subject at the present time. What would now appear to be wanted is that the example which he has set in taking actual measurements of insulation resistance should be widely followed. It is difficult to see that any really useful result is to be attained by the mere expression of opinion as to the best value to give to the insulation coefficient. What we do want is a wide collection of data from actual practice; in this way only can we discover not merely what ought to be done, but what can be done, and what is being done under the conditions with which contractors have actually to deal. If Prof. Jamieson's Paper leads to such a result it will be difficult to overestimate its value. Since, however, it is to be reconsidered before opportunity has been allowed for further practical observation, we trust that no effort will be wanting to make the discussion worthy of the importance of the subject.

There is one point of considerable importance on which we are inclined to disagree with Prof. Jamieson. Speaking of

Digitized by Google

testing with a Wheatstone bridge, he says that if a sensitive mirror galvanometer be employed, "the battery power used need only be a few Leclanché cells (10 or 12 at most)." Now apart from the practical inconvenience (amounting, in fact, almost to an impossibility) of bringing the mirror galvanometer into regular use for such a purpose, we are of opinion that the only really valuable test would be one made with an E.M F. considerably higher than that which the insulation will afterwards be subjected to. And, more than this, the current should be kept on the wire for some considerable time. In this case the galvanometer need not be very sensitive; but the difficulty is of course to get the high voltage. On this point we venture to make a suggestion. It would seem a comparatively simple matter to build a small magneto, with the armature geared to a train of wheels, and arranged to be driven by a weight. It would even be easy to get different E.M.F.s at pleasure by employing a suitable weight as the driving power. It is not our business to go into details, but at present we can see no reason why this should not be done, and it would certainly be far more satisfactory than any method of testing with an E.M.F. perhaps less than 10 per cent. of that which the insulation will be required to stand.

THE Committee of the Institution of Electrical Engineers, which has been appointed at the request of the Board of Trade to confer with it upon the question of overhead wires, is displaying a commendable activity, and already four meetings have been held. Meanwhile the Electrical Trades Section of the L.C.C. is also taking steps to secure a representation of its views before the Board of Trade. Seeing that this is rather a commercial and an engineering than a scientific question, it would seem to have been an oversight on the part of the Board not to have invited the co-operation of the Section.

IT will possibly cause some little surprise to the "local authorities" to learn from a Board of Trade circular that (in the absence of a Provisional Order) they possess no power whatever to grant permission to an electric supply company to place its mains under any "public highway." When the Board of Trade were asked this very question (in December last) by the Ipswich Town Council they were not in a position to reply; since that date they have, however, been advised that the above is the interpretation of the law. It is, moreover, clear that any other interpretation would have done violence to the spirit of the Electric Lighting Acts, whereby the Board of Trade is constituted the sole abiter in all projects for the public supply of electricity, subject, of course, to the confirmation of Parliament. Where the procedure is by Provisional Order the Board of Trade may grant such Provisional Order in despite of the local authority, though the latter may subsequently oppose its confirmation by Parliament.

IT is clear, however, that this circular is chiefly intended as a warning to those Supply Companies who are investing their money in schemes which have not received the sanction of the Board. The existing condition of affairs has, in fact, compelled the Board of Trade to place itself in a position to ignore, if it should think fit to do so, the vested interests which are now being rapidly created. *Beati possessores* is no doubt a legal maxim, but those who attempt to secure a footing in any other way than that provided by the law of the land must be prepared to face the consequences of their temerity. This notification will probably have some tendency to check the present display of activity, but the delay will only be of a temporary character, and will, doubtless, eventually enable every one of the companies who are at present in the field to go ahead with a clear conscience. Anyhow, it was clearly impossible for the Board of Trade to have acted otherwise than it has done.

MR. ACHESON'S photographic experiments, to which our New York correspondent referred last week, seem to have attracted a good deal of attention in the States; but although they are interesting in their way, we fail to see that any new light has been thrown upon the subject. Mr. ACHESON seems to have thought that if he could prove the existence of a time interval between the A and B sparks Dr. LODGE'S theory of the alternative path would be upset. But in accordance with that theory we should expect to find an interval of one-quarter of the oscillatory period when the B spark is at a maximum, and less when the B spark has less than its maximum length. In the absence of information as to the time constant of the circuit it is difficult to judge whether the spreading of the B spark on Mr. ACHESON'S plates could have been due to the displacement indicated. Dr. LODGE'S views, moreover, have passed the test of mathematical analysis; Mr. ACHESON'S have still to be submitted to this ordeal.

THIS week's instalment of Dr. FLEMING'S "Notes on Electro-Magnetic Induction" deals with one of the most interesting of the many interesting results obtained by Prof. HENRY nearly half a century ago. We doubt whether there are a dozen electricians living to-day who were aware of the singular and important effects of "screening" action. The facts will probably be found to be by no means unimportant in the practical development of alternating-current apparatus. The researches of Prof. HENRY would seem to have passed into a wholly unmerited oblivion until they were not only resuscitated by Dr. FLEMING but also interpreted and expounded in accordance with modern theory.

As the English Patent Laws are often compared unfavourably with those of the United States, it is interesting to notice how the comparison looks when viewed from the other side of the Atlantic. The New York *World*, in a series of sensational articles, has lately been giving the United States Patent Office an "airing," and if half of what is alleged against them be true, both office and officers are much in need of it. The charges of fraud and maladministration with which the *World* liberally bespatters the officials are, however, without much substantial evidence to back them. But the Patent Laws themselves appear to work badly, noticeably where they differ most from the British. It is often complained that our indiscriminate system of granting patents lends a fancied security to the poor inventor, tempting him to costly

Digitized by Google

expenditure, with the result merely of swelling the Patent Office revenue. In America, on the other hand, where a rigid preliminary examination is instituted, the "poor inventor" has very little chance of a hearing, the examiners considering it their duty to pluck as many candidates as possible; and so much time is occupied in the process that the invention is often rendered useless, or is forestalled by some wealthier and more dexterous applicant.

ANOTHER mischievous system pertains to the United States Patent Laws, which may be worked with great injustice both to the inventor and the public. Briefly, it amounts to this, whenever a valuable patent is obtained some rich company is pretty sure to find out that the invention is not new, and then lends its support to the "prior inventor." If the patentee is poor he is incontinently snuffed out; if rich, both claimants agree to keep up a contest of claims, the Patent Law meanwhile granting both security until their dispute is settled. When this can no longer be delayed the two combine in one "basic" patent, the effect of which is to secure a term of seventeen years' protection *plus* the years during which the parties have been playing at litigation. The *World* alleges that this is the meaning of what has been going on in connection with the telephone patents in America, and that we shall presently hear of an agreement under which a fresh lease of life will be sought for the disputed patents, although they have enjoyed exclusive rights already since 1876.

The West Indies and British Guiana Cable.—We are informed that the cable between Punta Rassa and Key West is interrupted.

The Bessbrook Tramway.—During the past year 97,668 passengers and 12,206 tons of goods have been conveyed over the Bessbrook Electric Tramway.

New Mexican Cable.—Advices from the city of Mexico state that a second cable is to be laid between Vera Cruz and Galveston during the present spring.

Nottingham.—An electric lighting company is now being formed in connection with a London company for the purpose of supplying the town with electricity.

The New Edison Stations.—The *Electrical World* of January 19 contains an excellent description, with illustrations, of the new "uptown" Edison Stations at New York.

The Electric Light in Brazil.—The municipal authorities of Inez de Fora have ordered from the Westinghouse Company of New York the necessary plant for lighting the city by electricity.

The Cupidoscope.—Messrs. J. and C. B. Gibson, of Edinburgh, have brought out an amusing electric apparatus called the "Cupidoscope," which will probably afford much entertainment at evening parties and other social gatherings.

Wolverhampton.—A company is being formed at Wolverhampton for the purpose of supplying the electric light on the house-to-house principle. We understand that Messrs. Elwell-Parker will provide the necessary plant for the first central station.

Electrical Science in Spain.—We have received the first number of a fortnightly journal, entitled *Anales de la Electricidad*, which is issued in Barcelona under the directorship of Dr. Antonio Suarez Saavedra, a name well known in this country.

St. James's Vestry.—At a meeting of this Vestry last week some discussion occurred with reference to the assessment of the premises occupied by the St. James's and Pall Mall Electric Light Company. It was generally agreed that the question of assessment was rather premature, and the matter dropped.

Crompton and Co.—Following a well-established custom, the wives and children of the *employés* of Messrs. R. E. Crompton and Co. were recently invited by Mrs. Crompton to a tea and entertainment in the large joiners' shop of the firm of Crompton and Fawkes. The company numbered about 400, of whom 290 were children. No effort was spared to make the affair a success.

Lambeth Vestry.—At the last meeting of this Vestry a report was read from the Electric Lighting Committee with respect to the applications made by the London Electric Supply Corporation and the Metropolitan Electric Supply Company for Provisional Orders for Lambeth under the Electric Lighting Acts. The committee recommended the Vestry to oppose both the applications. The Vestry adopted the committee's recommendations.

Electric Lighting in New Zealand.—We learn that Mr. J. Ewing is about to light Vinegar Hill, near Dunedin, New Zealand, by electricity. Arc lights of 2,000 candle-power will be used, and supplied with current from dynamos manufactured by Messrs. Elwell-Parker, of Wolverhampton, the machines being driven by Pelton water-wheels under pressure of 400 feet per head. The Cromwell Q.M. Company at Bendigo Gully, lately lit by the same firm, is now in full operation with satisfactory results.

Mr. Halliday's First Course of Mechanical Drawing.—With reference to our review of last week, Mr. Halliday writes us as follows:—"Allow me to thank you for the appreciative notice which you have given of my book on page 368 of *The Electrician*; but I shall be glad if you will allow me to point out that while the book is my own, the idea of making tracing a first course of mechanical drawing is Prof. Perry's, and the system was in successful operation here and in Japan for at least seven years before I came to the college."

St. Thomas, Charterhouse, Boys' School.—The Clothworkers' Company's Technical Scholarship, of the value of £130, has just been awarded to Walter C. Mears, a pupil of the above school. The scholarship is given for proficiency in mathematics, science and drawing, and is held at the Technical College, Finsbury. It has now been won for several years in succession by pupils of this school. It will be remembered that a short time ago another pupil won a Saddlers' Company's Scholarship of £60, and seven others passed the Matriculation Examination of the City and Guilds of London Technical College.

The Bressa Competition.—The Académie Royale des Sciences of Turin announce the close of the competition for the Bressa Prize for the greatest scientific discovery or work during the years 1885-88. This prize was only open to Italians. The Académie at the same time remind the public that a second competition is now open. According to the will of the late Dr. C. A. Bressa this second prize may be competed for by savants of all nations; the value of the prize is 12,000fr., and will be awarded to the most brilliant or useful discovery or to the most celebrated scientific or historical work of the period 1887-90.

St. Luke's Vestry.—On Tuesday afternoon last week the members of the St. Luke's Vestry met specially to consider the proposals of the London Electric Supply Corporation. The Parliamentary and Improvement Committee brought up recommendations favourable to the proposals provided they were carried out by fully authorised and competent companies. They also recommended that a limit be placed upon the time of carrying out the work after powers were obtained, and that there be a sufficient deposit of money in the hands of the Vestry to recoup them for any expenses in reinstating the public ways which might be disturbed for the laying of the system. These suggestions were agreed to unanimously.

An Electric Date and Time Stamp.—An ingenious apparatus by which date and time can be stamped on any document has lately been brought out by a Mr. C. Adams-Randall. The mechanism simply consists of five type wheels disposed on a single axis, and the minute, the hour, the month and the year

Digitized by Google

are automatically placed in line under the impression pad. Motive power is obtained by means of a couple of Leclanché cells, actuating an electro-magnet, which puts tension on a spring and moves the minute wheel. Upon the sixtieth movement of this wheel the hour wheel is automatically moved, and so on. The apparatus can be set in motion in connection with any clock. Its first application in this country has been made by the Commercial Cable Company.

Brisbane.—A correspondent at Brisbane informs us that Messrs. Trackson Brothers are actively pushing the telephone in that city. The Bundaneba coal mines have a very complete telephonic installation, the whole of the wiring being in lead tubing on account of the damp. Several large Government offices have also been provided with telephones. At the rifle ranges belonging to the Defence Force the markers and the various firing points are telephonically connected, and the arrangement has given great satisfaction. Another telephone line connects Walloon Station to Marbery Scrub, a distance of 14 miles. Messrs. Trackson Brothers have also put in three small electric light installations during the past year, each of 50 lights, one in a mine and two in sawmills. Parliament House, the Government printing office, and the railway station are lighted by Edison plant.

Globular Lightning.—In a letter to *L'Océan* M. de Paulpiquet gives an account of a somewhat remarkable globular discharge, which was witnessed by him on the evening of the 30th of November last, as he was driving home from Brest. At the height of the storm M. de Paulpiquet suddenly perceived a dark red glow in front of him, caused by a hemispherical body which had fixed itself on to the horse's chest, a little to the right. The part of the hemisphere turned towards the road, however, lit it up with a dazzling white glare. The horse stumbled several times, and on the last occasion the ball burst, killing the horse on the spot. A large oak on the side of the road had been struck and torn open from top to bottom. M. de Paulpiquet was uninjured, but the servant at his side got a severe shock, and a boy who was behind him was thrown out of the trap, and still suffers from a burning sensation in his right ear.

The Centenary of Ohm.—As we mentioned in our last issue a meeting was held on Thursday last week in the meeting-room of the Royal Society, under the presidency of the Right Hon. Lord Rayleigh, for the purpose of appointing a committee to co-operate with the committee formed in Germany to promote the erection in Munich of a statue of George Simon Ohm. The following gentlemen were selected to act on the English committee:—Sir F. Abel, D'Atkinson, Mr. Vernon Boys, Mr. Conrad Cooke, Profs. Ewing, Fitzgerald, Fleming, G. Carey Foster, Mr. Glazebrook, Prof. D. E. Hughes, Mr. Norman Lockyer, Profs. Hugo Müller, John Perry, Mr. W. H. Preece, Lord Rayleigh, Profs. Reinold, Rücker, Stokes, Mr. Swinburne, Sir William Thomson, and Prof. S. P. Thompson. Lord Rayleigh was elected President, Prof. Hugo Müller treasurer, and Prof. G. Carey Foster and Prof. John Perry undertook to perform the duties of secretaries and to receive subscriptions.

The Hanover Square School of Electrical Engineering.—In consequence of the recent re-organisation of the advanced instruction, which is now under the charge of Mr. Charles Capito, M.I.M.E., the managers recently requested Mr. Gisbert Kapp to undertake the examination of the advanced class. One day was devoted by him to an examination in practical work, such as engine-running, boiler-firing, dynamo and lamp management, joint-making, &c., and a second to Papers on mechanical and electrical engineering. Out of seven students examined, three were awarded the certificate of the school, Messrs. Hawkins, Rowlett and Graves; the average percentage of marks gained by them being respectively 87·8, 78·8 and 65·8. A minimum of 70 per cent. in the practical work, and 60 per cent. in the two Papers, is a necessary condition of obtaining the certificate. We may add that, as the result of former examinations, Mr. Fletcher has also recently gained the certificate.

St. Catherine's Lighthouse.—In this week's *Graphic* appears a two-page sheet of admirable sketches of St. Catherine's Lighthouse and its electrical machinery. One in particular shows the lamp, with its fluted carbons, 2½in. diameter, six-pointed star shaped. Upwards of 20 electrical horse-power are consumed in this one single arc, and as absolute steadiness of the arc is vital to the optical requirements of the lantern the form and quality of the carbons become of the utmost consequence. This fluted form of star-shaped section was originally proposed by Sir James Douglas, and its use at St. Catherine's for the heavy currents of upwards of 300 amperes has contributed in no small degree to the success of the light. The carbons are supplied to the Trinity House by Messrs. Lacombe and Co., of Westminster. Fluted carbons are now much in favour for use in projectors and search lights with large currents. We may add that the St. Catherine's Lighthouse was described in *The Electrician* of July 13, 1888, p. 297.

Brighton.—A special meeting of the Brighton Town Council was held on Wednesday, the 30th ult., to receive a report from the General Purposes Committee with reference to the application of the Brighton Electric Light Company (Limited), for a Provisional Order under the Electric Lighting Acts, 1882 and 1888. The committee reported that they had considered the matter carefully, and found that there were many serious objections to the provisions of the Order, such as the continuance of overhead wires, and the proposed system of charging for electricity. The most serious question, in the view of the committee, was that of the breaking up of the roads and pavements. Attention was also drawn to the fact that in 1883 the Corporation had obtained a Provisional Order, but that the powers of the Order had not hitherto been exercised, in consequence of the uncertainty surrounding the question. The committee was further of opinion that the Council might shortly be able to commence the supply of electricity without incurring serious risk of loss. The committee considered that the Council should refuse their consent. After some discussion this motion was carried.

Electric Motors for Felling Trees.—Hitherto machines for felling trees have been driven by steam power, but this is sometimes inconvenient, especially in thick woods, and electric power has recently been adopted in the Galician forests. Usually in such machines the trunk is sawn, but in this case it is drilled. When the wood is of a soft nature the drill has a sweeping motion and cuts into the trunk by means of cutting edges on its sides. The drill is actuated by an electric motor mounted on a carriage, which is brought up close to the tree and shackled to it. The motor is capable of turning round its vertical axis; and the drill is geared to it in such a manner that it can turn through an arc of a circle and make a sweeping cut into the trunk. The first cut made, the drill is advanced a few inches and another section of the wood removed in the same way until the trunk is half severed. It is then clamped to keep the cut from closing, and the operation continued until it would be unsafe to go on. The remainder is finished by a hand saw or an axe. The current is conveyed to the motor by insulated leads brought through the forest from a generator placed in some convenient site.

An Application of Electricity to Mining.—In a Paper recently read at a meeting of the Ohio Institute of Mining Engineers reference was made to applications of electricity in mining, and the installation of electric power at the Drain Colliery, Osceola, Pennsylvania, was brought forward as a recent successful instance. In this colliery there is an electric motor for the operation of a coal cutter of the type and patent known as a "Lechner Hercules." In this installation a 10-horse-power motor is mounted on a truck, which is placed on the mine tramway, and as the motor weighs less than 1,000 lbs. it is easily moved as the occasion requires. The motor is connected with the cutter by a tarred hemp rope, the connection being of sufficient length to operate the cutter at a distance of 30 feet. The dynamo generating the current is 1,600 feet away from the motor. Only two men are needed to operate the plant, and these two men excavate 100 tons each ten hours. Seventy per cent. of the primal energy is given off for work from motor pulley to the cutter. The cost of the electrical equipment for this service, including generator, conductors, and motor, was £325. The installation was put in by the engineers of the Sprague Company.

The Occlusion of Gases in the Electrolysis of Sulphate of Copper.—In a recent number of the *Comptes Rendus* M. A. Soret has a Paper giving the results of his investigations into the occlusion of gases by electrolytically deposited copper, which, in view of the development of the Elmore process, possesses an additional interest. In very dilute solutions, says M. Soret, a muddy deposit is usually obtained unless the current density is small; this muddy deposit probably contains a certain amount of copper hydrate. In concentrated solutions, on the other hand, this brownish-black deposit is not found unless the current density is excessive. The deposit is generally bright and metallic, but its degree of malleability is very irregular, being dependent on the temperature and acidity of the electrolyte. Lenz noticed the presence of gases, especially hydrogen, in electrolytically deposited copper, and the result of the analysis of a very brittle deposit gave the proportion of gas at 4·4 volumes. M. Soret's investigations have led him to the following conclusions: 1. Electrolytically deposited copper always contains a certain amount of gas which consists almost exclusively of hydrogen; it also contains a little carbonic acid, and at times a very feeble trace of carbonic oxide. 2. There is a certain relation between the quantity of gas occluded and the temperature and acidity of the solution, which in turn affect the malleability of the metal. 3. In consequence of this relation the gas occluded is a variable quality, and the figure given by Lenz can only refer to the particular case then under consideration. In no case did the hydrogen occur in other than an occluded condition. M. Soret adds: "I propose to follow up these researches upon the following lines: Electrolysis will be performed in concentrated solutions, containing variable amounts of free acid and kept at perfectly constant temperatures during the experiments; the deposited metal will then be submitted to a high temperature in vacuo, and the gases given off will be analysed.

Dr. Lummer's Photometer.—Before a recent meeting of the Berlin Physical Society, Dr. Lummer read a Paper on Photometers, and deduced, from the experiences gained with the existing instruments, the following as requirements in their construction: in the first place, the surfaces whose brightness of illumination is to be equalised must not be separated by even the narrowest intervening space; and in the second, the outline of the surfaces must be sharply defined. The first of the above requirements is satisfied in Bunsen's grease-spot photometer, but not the second. A further drawback arises from the fact that the grease-spot reflects light, and the paper allows some to pass through, so that both the spot and the surrounding surface are always illuminated by both sources of light. An ideally perfect photometer ought to reflect no light from its grease-spot, and be impermeable to light over the rest of its surface. The speaker, working in conjunction with Dr. Brodhun, had obtained the above desiderata by purely optical means. When two total reflection prisms are placed with their hypotenuse surfaces in juxtaposition, and two of the surfaces of the glass-cube thus formed are illuminated by light from bright surfaces, then on looking through the combination of prisms the only light which reaches the eye will be that which enters laterally, whereas that which enters from the opposite side cannot reach the eye. When a drop of Canada-balsam, whose refractive index is very nearly the same as that of the glass, is placed between the opposed hypotenuse surfaces, total reflection is done away with at the place where the drop lies, and thus by illumination from *one* side only a bright spot is seen on a dark ground or a dark spot on a bright ground. When the illumination is made from *both* sides, equality of illumination can be easily established by adjusting the relative distances of the sources of light until the spot disappears entirely. The drop of Canada-balsam very soon loses its sharply-defined edges, hence some other mode of procedure became necessary. The central portion of the hypotenuse surface of one of the total reflection prisms was left untouched, while the rest of the surface was ground to a slightly spherical shape. When the surfaces of the prisms were now firmly pressed together, light passed without hindrance across the point of close contact of the surfaces, whereas it was totally reflected at all other points. By this means an ideally perfect "grease-spot" was obtained, which was permeable to light, but reflected none, while the surrounding area reflected light completely and allowed none to pass through. A third method for obtaining an ideally perfect grease-spot consisted in etching figures on one of the reflecting surfaces of the prisms; the etched portions were perfectly transparent, the rest of the surface reflected light completely. The speaker exhibited photometers constructed according to the above methods, and proved theoretically that the ideally perfect grease-spot bears to the real one the ratio of 1 to 2, according to the constants determined in the Imperial Physico-Technical Institute. The sensitiveness of the new photometer is about 1 per cent.

Electric Lighting in Birmingham.—After a prolonged consideration of the proposed electric lighting scheme, referred to them for investigation, the General Purposes Committee of the Birmingham Town Council have decided to recommend the Corporation not to give its sanction to the Electric Light and Power Order applied for by Messrs. Arthur Chamberlain and George Hookham unless they consent to the modifications suggested by the committee. The Order contained two areas, schedule A comprising the principal business streets of the city, schedule B containing the whole of the city area, for purposes of extension. The main subject of disagreement centred upon the question of giving the undertakers at the outset powers embracing the entire area of the city. The view of the sub-committee was that the area should, in the first instance, be limited to one of the scheduled districts until the enterprise had been sufficiently tested by practical experience. Among the incidental objections taken to the scheme was the fixing of the capital, in the event of a limited liability company being formed, at not less than £50,000. In the opinion of the sub-committee the capital should be double that amount for schedule A alone. It was also thought that the deposit of £1,000 was too small in consideration of the fact that, under the third paragraph of section 9, the sum deposited was to be released when equal amounts had been expended on works. As a security for execution of works, Messrs. Chamberlain and Hookham offered to postpone exercising the powers to be given them by the Order until they have expended in premises, machinery, plant, and instruments a sum not less than £17,500, or until they have assigned the undertaking either to an existing or newly formed company of a private nature in which capital of not less than £50,000 shall be specially hypothecated against works. Of this offer no notice was taken by the committee. Another difference of opinion arose on the facilities to be given to the local authority for the testing of the light. The Chelsea Electric Light Order of 1886, to which appeal was made on different points, provided for the inspection of the insulation and conductivity of the electric lines, the efficiency of the joints, and for making such tests as might be approved of by the Board of Trade and for certifying meters. The draft Order promoted for Birmingham, however, omitted everything except the certifying of meters and the testing of pressure at the testing stations to be provided by the local authority. It also omitted the section of the Chelsea Order in which the undertakers are to set up and maintain proper instruments, and keep records of observations therefrom, upon all premises from which they supply electricity, such instruments being subject to inspection by the local authority. The committee also considered the question of overhead wires, and decided that they should not be allowed, and they would not be prepared to approve of any scheme in which overhead wires were contemplated. In connection with this matter, the committee discussed the proposal of the promoters of the Provisional Order to sell to the Corporation their undertaking within two years from the date of the Order being obtained, and came to the conclusion that there was nothing in the offer to induce them to recommend it to the Council. Mr. Henry Lea, technical adviser to the committee, pointed out in the course of his report the several objections which exist with regard to small central stations in the heart of the town, and suggested that the Corporation ought to work on the lines of the Deptford scheme whenever they seriously considered the question of themselves undertaking the supply of electricity. On Tuesday last the proposals of the General Purposes Committee came before the Council, and, after a long discussion, they were agreed to.

NOTES ON ELECTRO-MAGNETIC INDUCTION.

BY DR. J. A. FLEMING, M.A.

(Continued from page 302.)

When Prof. Henry obtained possession of the "Experimental Researches" of Faraday, as detailed in the fourteenth series of his "Experimental Researches," he was exercised in his mind to reconcile the results obtained by Faraday on the interposition of metallic screens between inducing and induced circuits with his own. Faraday had found that when the galvanometer was used as a current finder "it makes not the least difference" whether the space between the primary and secondary coils was air, sulphur, shellac, or such conducting bodies as copper and other non-magnetic metals. On the other hand, Prof. Henry found that a shock from a secondary coil which would paralyse the arms was so much reduced by the interposition of a metallic plate as hardly to be sensible on the tongue. Here was evidently something to be explained, and in a long memoir (*Phil. Mag.*, Series 3, Vol. XVIII., 1841, p. 492; also *Transactions* of the American Philosophical Society, Vol. VIII., 1840) Prof. Henry examined this and other matters. He first verified Faraday's experience by attaching the ends of a secondary coil to a galvanometer and bringing up suddenly towards it a permanent magnet, or a coil traversed by a steady current. The swing of the galvanometer was found to be quite unaffected in extent by the interposition of a plate of copper. Again, in place of the copper plate, a closed metallic conductor (an endless coil) was employed, but whether the circuit of this coil was open or closed it made not the slightest difference on the galvanometer deflection.

Forty feet of copper wire, covered with silk, were wound on a short cylinder of stiff paper, and into this was inserted a hollow cylinder of sheet copper, and into this again a rod of soft iron. When the latter was rendered magnetic, by suddenly bringing in contact with its two ends the different poles of two magnets, a current was generated in the wire, but the strength of this current, as measured in the galvanometer, was the same whether the copper cylinder was present or was removed. Prof. Henry then noticed that there was one element of difference between the indications of a galvanometer and that of the magnetising spiral. If the two secondary currents at "break" and "make" of a primary were sent through a magnetising spiral and through a galvanometer, the arrangement might be such that the induced current at "make" of the primary was unable to give any sensible magnetisation to the steel needle enclosed in the spiral, but at "break" was able to magnetise it to saturation. Nevertheless, in both cases the "throw" of the galvanometer was the same. Similarly with the degree of shock felt, the galvanometer indications being alike for the inverse and direct induced current; yet that induced current gave the greatest shock which was able to produce the greatest magnetisation. The explanation of these facts became clear as soon as it was seen that the deflections of the galvanometer depended upon the whole quantity of the discharge, and must necessarily be alike for the inverse and for the direct current, but that the magnetising effect and the physiological shock depended upon the maximum value of the instantaneous discharge current, and might therefore be very different for the two induced currents. It was then evident that any actions by which this maximum value of an induced current was decreased, whilst its duration was increased and total quantity left unaltered, would result in rendering this current less easily detectable by shock or magnetisation, but make no difference in its effect on a galvanometer. Aided by this thought, he repeated Faraday's experiment with the balanced coils referred to in § 8 ("Experimental Researches," Vol. I., § 1,790 *et seq*). A galvanometer was provided having two equal wires of the same length and thickness wound on the same frame, and also a double magnetising spiral was prepared by winding two equal wires round the same piece of hollow straw. Coil No. 1, connected with a battery, was supported perpendicularly on the table, and coils Nos. 3 and 4 were placed parallel, one on each side, and each coil connected in series with one coil of the differential galvanometer and with one spiral of the magnetising helix. The two outside coils were then adjusted so that when the battery circuit was made and broken, and the current started and stopped in the middle coil, no indication was given by the galvanometer, and no magnetisation produced in a steel needle placed in the double helix. A thick zinc plate was then introduced between the primary coil and one of the secondaries, and it was found that the needle of the galvanometer still remained stationary on making and breaking the primary current, but that the steel needle in the spiral became powerfully magnetic. This indicated that the two secondary currents, whilst still equal in total quantity, had been so affected that one had a less maximum value than the other, and hence a differential magnetising action was produced. A similar effect was observed when a galvanometer and magnetising spiral were together introduced into the secondary circuit of a single primary and secondary circuit. The interposition of a metal sheet considerably reduced the magnetising power or the shock, but left the galvanometer deflection unaltered. In order to increase the number of facts, this last experiment was varied by the exchange of a soft iron needle for the hard steel needle in the magnetising coil, the metal screen being interposed in each case, and it was found that whereas the metal screen cut off almost entirely the power of the secondary current to magnetise hard steel, it could yet slightly magnetise the soft iron. A screen of cast iron, half an inch thick, however, not only neutralised the power to magnetise hard steel, but reduced the deflection of the galvanometer as well. The general explanation of the foregoing facts, as due to Henry, is as follows:—The secondary current, as we have seen, is a brief discharge, which rises very suddenly to its maximum value and then fades gradually away. The current curve of the secondary current, due to the rupture of a primary circuit, may be represented by the thick firm line in Fig. 25. If a metal screen is interposed between the primary and the secondary circuit the screen gets a similar secondary current generated in it, and this last again acts by induction to generate a tertiary current in the secondary circuit. This tertiary current consists of two portions—first, an inverse part opposite in direction to the secondary current in the screen, and, secondly, a succeeding direct current. Let the current curve of this tertiary current in the secondary circuit be represented by the fine firm line in Fig. 25. The total quantities of electricity flowing in each part of the two portions of the tertiary current are equal. The resultant effect, then, of the action of the primary current when interrupted is to cause in the secondary circuit the true secondary current, which is an unidirectional flux (thick curve), and a superimposed tertiary current, which is a bi-directional flux, its algebraic total of quantity being zero:

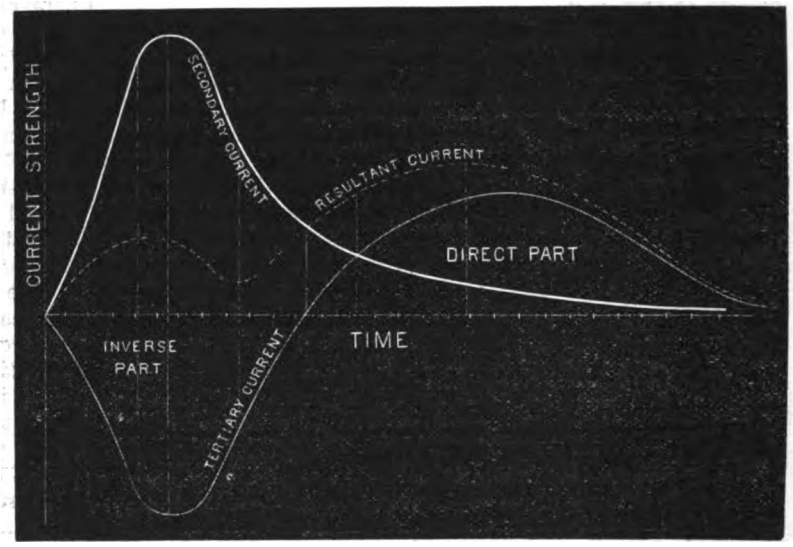

FIG. 25.

Digitized by Google

If we add together at each instant the ordinates of the two current curves we get a resultant curve (dotted line) which represents the actual current curve in the secondary circuit. The total area (electric quantity) enclosed between the horizontal line and the dotted curve must be equal to the total area enclosed between the thick firm line and the horizontal, because we have added and subtracted equal areas; but the *maximum* ordinate of the dotted curve will be less than that of the thick firm line curve, and the *form* of the curve will be very different also. It is, then, clear that the superposition of a complete tertiary current, which is of itself but very little able to affect a galvanometer on a secondary current which gives a definite galvanometer indication, is not able to alter that galvanometer deflection, depending as it does on the total quantity of the discharge. The magnetising power and shock, however, depend upon the maximum value or suddenness with which the induced current rises to its maximum value, and this factor is very much affected by the overlaying of a secondary current by a tertiary. We see, then, that the experiences of Faraday and Henry may be completely reconciled, and that magnetic screening is a phenomenon which in this case depends upon the nature of the detecting instrument in the secondary circuit.

Reaction of a Closed Secondary Circuit on the Primary—If a Bell telephone is placed in series with a coil of many turns of fine wire wound on a hollow bobbin, and if both are placed in series with the secondary circuit of a small induction coil, the strength of the secondary current can be so adjusted that the telephone emits a low murmur or rattle. This being the case, let a solid bar of copper be introduced into the bobbin of fine wire, and it will be found that the noise of the telephone is *increased*. If a bundle of fine iron wires is substituted for the copper rod, it will, on the other hand, *reduce* the noise or stop it altogether. The explanation of this effect is to be found in the reaction which a closed secondary circuit has upon its primary in reducing the impedance of the primary. We have shown in an earlier chapter that the re-active effect of the secondary is to increase the resistance and reduce the inductance of the primary circuit, and we have deduced two formulæ given by Maxwell for the value of the equivalent resistance R′ and the equivalent inductance L′ of a primary coil of resistance R and inductance L in the presence of a secondary coil of resistance S and inductance N, the magnetic circuit having a constant resistance, and the mutual inductance being M. Hence the equivalent impedance $I m'$ of the primary coil in presence of the secondary is $\sqrt{R'^2+p^2 L'^2}$, and its isolated or intrinsic impedance is $I m$ equal to $\sqrt{R^2+p^2 L^2}$. The question is, which is the greater—$I m'$ or $I m$? To discover this, take for R′ and L′ the values given on page 337 (*Electrician*, Vol. XX.), and we have

$$R' = R + \frac{p^2 M^2 S}{S^2+p^2 N^2},$$

and

$$L' = L - \frac{p^2 M^2 N}{S^2+p^2 N^2}.$$

Forming from these the function $R'^2+p^2 L'^2$, we have

$$R'^2+p^2 L'^2 = R^2+p^2 L^2 + \left[\frac{2p^2 M^2 R S - p^4 M^2 (2 L N - M^2)}{S^2+p^2 N^2}\right]$$

or

$$(I m')^2 - (I m)^2 = \frac{2p^2 M^2 R S}{S^2+p^2 N^2} - \frac{p^4 M^2 (2 L N - M^2)}{S^2+p^2 N^2}.$$

If $S = \infty$, or the secondary circuit is open, the right-hand side of the above equation is zero, and we find that the impedance of the primary circuit is not altered by the presence of the open secondary, as of course it should not be. If S is made very small, the value of the difference of $(I m')^2$ and $(I m)^2$ continually approximates to the value $-\frac{p^4 M^2 (2 L N - M^2)}{p^2 N^2}$.

Now, $L N - M^2$ is always a positive quantity if not zero, and the other quantities in this last fraction are squares. Hence the value of this last fraction is always a positive quantity if not zero. Hence it follows that if $I m'$ is not equal to $I m$ it is always *less* than it; in other words, the presence of the closed secondary circuit always diminishes the effective impedance of the primary. We have seen *loc. cit.* that the maximum value of the primary current for the induction coil without iron and with simple periodic impressed electromotive force applied to the primary circuit is

$$I = \frac{E}{I m'},$$

or

$$\text{Maximum current} = \frac{\text{Maximum E.M.F.}}{\text{Effective impedance of primary}}.$$

Hence, since the closing of a secondary circuit around a primary reduces its impedance it must also, if the primary coil is subjected to a constant impressed electromotive force, increase the flow of current through the primary. The explanation of our experiment with the copper rod is now simple. The introduction of the copper rod into the fine wire helix is equivalent to approximating to a primary coil a closed secondary circuit. The impedance of the fine wire circuit to the alternating current from the secondary circuit of the induction coil is hence reduced; it gets more current, and the telephone is made to emit a louder sound. If, however, a core of divided fine iron wire is introduced into the fine wire helix, the result is simply to increase the impedance of that circuit, and therefore to reduce the current actuating the telephone. When considering in particular the theory of the induction transformer as applied to electric distribution we shall see the above principles have important practical bearings.

(To be continued.)

ELECTRIC METERS FOR CENTRAL STATIONS.

(Continued from page 374.)

Aron's Meter (Fig. 3).—I now come to a very interesting type of meter, the principle of which was first suggested in this country by Professors Ayrton and Perry (applause), and which has been made a practical instrument by Dr. Aron, in Germany. I have lately visited the central stations of Berlin, the largest existing on the Continent, I should think, probably, the largest in Europe. These stations are the best equipped in the way of boilers, engines, dynamos, and accessories of any low-tension system I have ever seen. It is an extremely interesting station, or number of stations. Though there are three stations already at work (and two more to come), it is only one system altogether, because all the mains are connected together all over the place. There is this defect, however, that they have hitherto used a distributing system with two instead of three wires. Of course, in every case of low-tension distribution, the three-wire system ought to be used. This fault will be remedied in the future. The two other large stations which they are now putting down are going to be supplied by the three-wire system, and I presume that they have some arrangement for connecting with their present two-wire system, though I am not sure of the details by which that is going to be accomplished. They supply at present current sufficient for a maximum of 26,000 incandescent lamps of 16 candle-power. I beg to state that I have never found in the European stations that you have to divide by two the number of lamps which are stated to be used on the circuit in order to get the true number (laughter). I am utterly unaware of the reason, logical or moral, by which that course is supported in this country. But when I know a station using 16-candle lamps, and when I know of their counting the number of lamps which they say are supplied by exactly doubling the number which are actually in use, for the life of me I cannot understand what logic or morality there is in it (laughter.) It may be that they confess that their 16-candle lamps only give 8-candle power; but that is not the case, because they are speaking of the total number of 16-candle lamps they are able to supply. But there is a great tendency too, here in London, among a limited number to express a wish that we should have 8 candle-power lamps as a general rule instead of 16 candle-power lamps. All I can say against that is that at the present moment the so-called 16 candle-power lamps which we see in London are generally not more than 8 candles, and I never heard much satisfaction expressed with that (hear, hear). In the second place, it is the universal experience in hundreds of central stations in different parts of the world that the 16 candle-power is the practical standard with full pressure, and I do not see what ground we have to say that the 8-candle lamp has been found in practical experience to be a more suitable standard for ordinary consumption (hear, hear). I should be inclined to say let us rather go to 20 candles. As a general rule,

Digitized by Google

of course, there are places where 8-candle lamps can be used, and it is very desirable to have the means of putting in 8-candle lamps when you want them.

Now I return to the Berlin central stations. In addition to those 16 candle-power lamps of which I have spoken, the station of the Allgemeine Elektricitäts Gesellschaft also lights up the Unter den Linden with 108 arc lamps of 15 amperes, and the Leipziger-strasse with 36 arc lamps. The former is the finest piece of street lighting ever accomplished, not excepting the Avenue de l'Opera in Paris in the old days of Jablochkoff, which was very brilliant indeed.

All the incandescent lamps are charged for by meter, and the Aron meter is always used. Originally it consisted of an ordinary clock, with a permanent magnet for the bob of the pendulum; below this a coil of wire is fixed with its axis vertical. The current to be measured passes through this and repels the magnetic pole, thus diminishing the influence of gravity on the pendulum, and causing the clock to lose time. The loss of time in any period, as compared with a good, uninfluenced clock, shows the number of units of electricity which have passed through the instrument. It takes a long time to test such an instrument over its whole range, and I have not been able to obtain any tests. The chief inconvenience of the instrument in its old form was that a clock could not be depended upon for accuracy more than about half a minute a week. One minute a week would be the smallest registerable quantity. Suppose this means one lamp-hour, then the maximum loss of the clock in the week being 12 hours, the instrument could not register more than $12 \times 60 = 720$ lamp-hours per week. Another inconvenience was having to wind up so many clocks every week. The former defect has been got over by mounting two clocks on the same frame-work, one in its normal condition, the other governed by the current. The two trains of wheels are connected by a differential gear with a third train of wheels with dials and pointers like a gas-meter. This increases the range of the instrument, so as to be practical. Of course, this improvement diminishes the accuracy of the instrument, and has been found to do so in practice (1) by introducing more work for the clocks to do, and (2) by having to deal with the ordinary errors of two clocks; and every clockmaker knows that two pendulum clocks, mounted on the same frame, affect each other's going, and introduce errors. The principle of this meter is very beautiful, and in the Berlin central stations the authorities speak in very high terms of its value. Complaints from customers do come in, but in these cases the meters are tested, and found to work quite well. Its range is greater than for any other meter, being about 100-fold, I believe. I have two specimens of this meter, which have been kindly supplied to me by the General Electric Supply Company. One is of the modern type, with two clocks, working quite independently, with the two pendulums. In front you will see the counting mechanism, which is worked by differential gearing between the two clock trains underneath. We notice that the bob of the pendulum under one of them is a permanent magnet. Below the bob of the pendulum is a coil of wire through which the current passes. This repels the magnet and diminishes the effective gravity, and then the counting mechanism allows you to read it off quite easily. There is another type—that is the type for alternating currents—in which a coil is moving inside another coil, and the effect is of the same character.

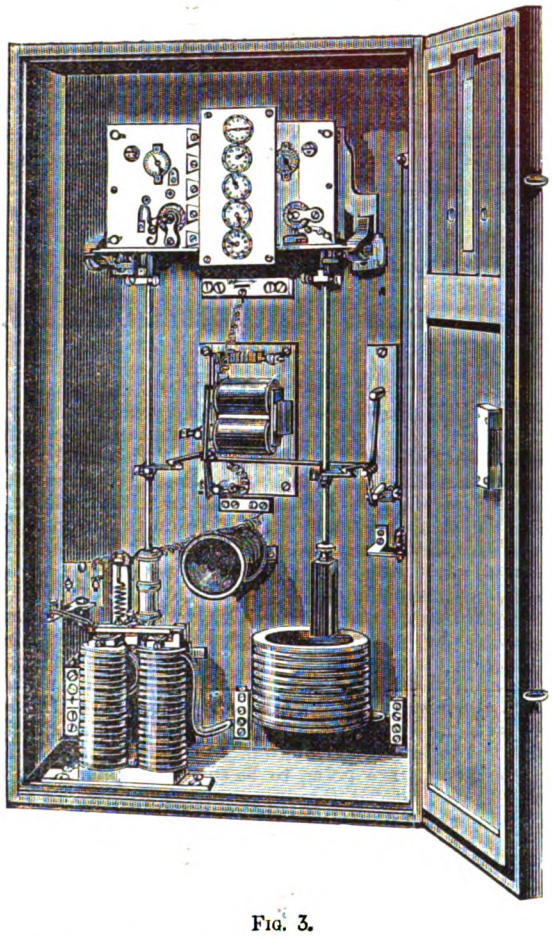

Fig. 3.

This meter has been altered, to adapt it for registering alternating currents, by replacing the permanent magnets by coils or electro-magnets. In the central station at Rome, which is in many points the finest and best designed station for alternating currents which I have yet seen, it is intended to test these meters. But I can say nothing about their accuracy. I will only point out that in this case the retarding influence would vary as the square of the current, whereas, with the permanent magnet, it would vary as the current. This does not lead us to hope for the same satisfaction as is undoubtedly given by the type for continuous currents.

Lowrie-Hall Meter (Fig. 4).—I will now say a few words about a meter specially designed for alternating currents, which resembles the Edison meter more than any other. This is the Lowrie-Hall meter. A battery—preferably a secondary battery—is placed on the secondary circuit of a transformer. An electrolytic cell is also placed in the circuit. Now there is no complete circuit through the battery and electrolytic cell except when the lamps are in circuit, and it is only then that electro-chemical decomposition can take place. The alternating current does not transfer metal from one plate to another. The whole effect in this way is produced by the battery, which acts as if the alternating current did not exist. Allow me to point out this by means of a diagram (Fig. 5). Suppose P to be the primary wire of a transformer and S the secondary, L being the lamp circuit. In the Lowrie-Hall meter a secondary battery, B, is put in series with the secondary coil; also an electrolytic cell, C, is inserted. Now, the alternating current which is passing through that circuit has no effect in decomposing the liquid, and, therefore, any effect is altogether due to this secondary battery. What is the quantity of current the electrolytic cell will measure? The quantity of continuous current which is flowing through the circuit depends upon the resistance of these lamps, and is proportional to the conductivity of the lamps, that is to the number of lamps that are on the circuit. It is an extremely

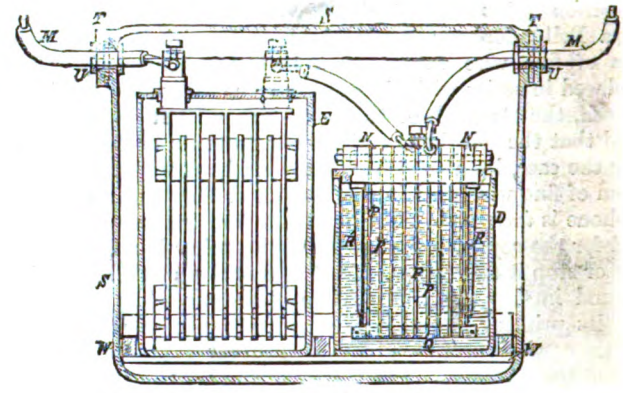

Fig. 4

S Case. P Plates.
E Secondary battery. T Terminals.
D Depositing cell

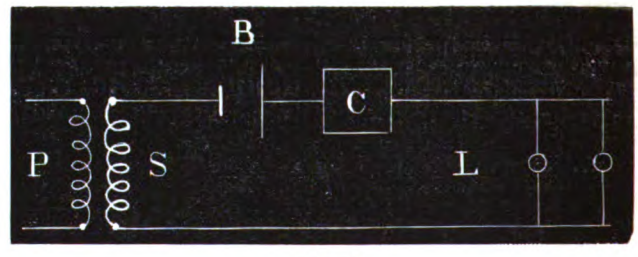

Fig. 5.

Digitized by Google

beautiful idea. Thus the total number of lamp-hours, or Board of Trade units, is measured by the quantity of metal lost by one plate or gained by the other. One is inclined to ask how long the battery will stand the alternating current, and whether there is much trouble in charging and replacing the secondary batteries. On those points I cannot speak personally, but I am informed that these meters have been successfully at work at Eastbourne for more than a year. As a further proof of the value which has been attached to the performance of this meter, I may mention that in the West Brompton Station of the House-to-House Electric Company the same meter is going to be used, owing to the successful experiments which have been made at Eastbourne.

Schallenberger Meter (Fig. 6).—A very practical form of meter has lately been brought out by Mr. Schallenberger, electrician to

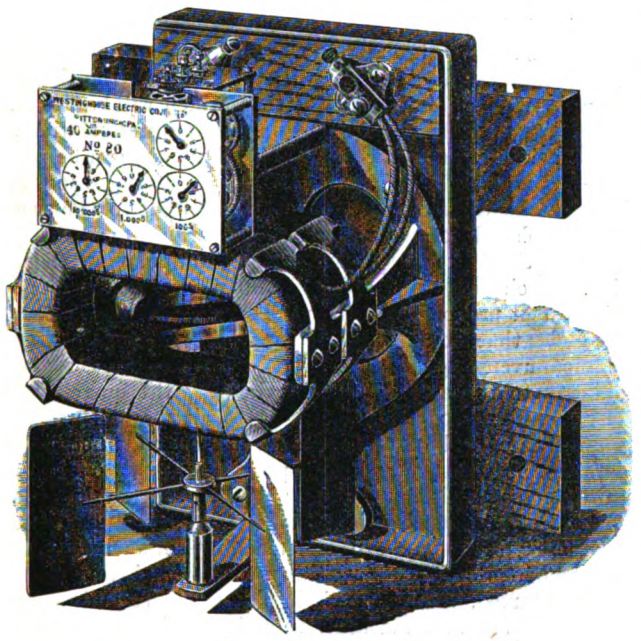

Fig. 6.

the Westinghouse Company at Pittsburg, an extremely ingenious and accomplished electrician. It also is intended for use only with alternating currents. This is not the place to go into a scientific

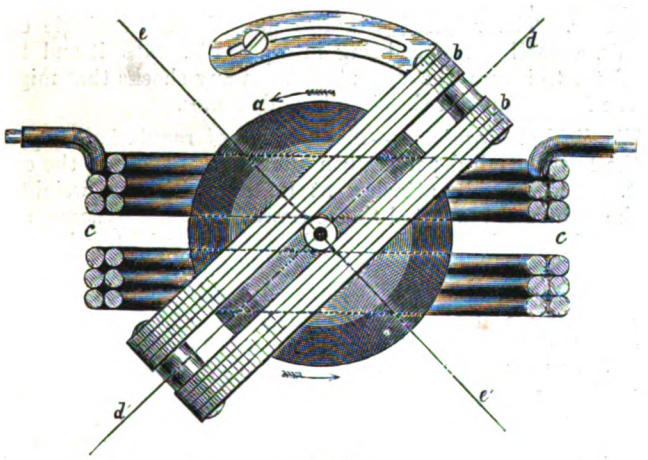

Fig. 7.

a. Flat ring of soft wrought iron.
b b. Copper plates, placed so as to surround the disc closely without touching it.
c c. Coil surrounding the whole.

examination of the theory of its action. I will try to explain it in popular language. I have here a diagram (Fig. 7) which shows in a sketchy way the general principle of it extremely well. Mr. Schallenberger is sending me one of these meters, but I am sorry to say that it has not arrived in time for me to be able to show you the meter itself. I will show you on the screen a photograph of it by the aid of the lantern presently, which will make it almost as distinctly visible as if I had the meter on the table. In the diagram we are looking downwards upon it. The meter consists essentially, in the first place, of a circular iron disc upon a vertical axis. This disc is, however, free to move, and it is connected with a train of counting mechanism. It also has upon the same axis fans to introduce air pressure to prevent the instrument from going ahead too fast. Two diameters of the circular disc are chosen inclined to each other at an agle of 45deg., and coils of wire are wound around on those two diameters. One coil of wire is short-circuited in itself, and is not connected in circuit. The other coil of wire, inclined at an angle of 45deg. to the first, carries the current which is to be integrated.

Now let me show you what action takes place. When a current is passing through this main circuit it induces a secondary current in the circuit which is inclined 45deg. to it, and this induced current attains a maximum a quarter of a period later than the maximum in the principal circuit. What then happens? First, the principal circuit attains a maximum and magnetises the iron disc. When the principal circuit falls to zero the secondary circuit attains its maximum, and tends to move the pole which has been created in the iron in a certain direction. When the principal current is going in the opposite direction it magnetises the disc in the opposite way.

It also induces a secondary current in the opposite direction; therefore the rotation of the disc will be in the same direction as before.

Thus, whether the current in the principal circuit is positive or negative the influence of the secondary circuit upon the pole induced in the iron is always such as to turn it in the same direction, and you have continuous rotation of the iron disc due to an alternating current in the principal circuit of the instrument (applause). This instrument acquires additional interest from the fact that it was invented and almost completed before the Ferraris or the Tesla motor (an instrument which was founded upon the same principle) was invented.

I think that one of the few objections which can be raised to this meter is that its indications vary with the speed of reversals of the alternating current; but every meter which is founded on magnetic action must have that defect. It is generally said that in practice the variation from this cause will not be more than one or two per cent. There is no doubt the meter remains a beautiful practical instrument, which is doing splendid work in the United States.

Forbes's Windmill Meter (Fig. 8.)—Some years ago, when I first realised the value of the invention of Messrs. Gaulard and Gibbs for distributing high-tension currents in the main and delivering it as low tension in the houses, I felt that one difficulty in the

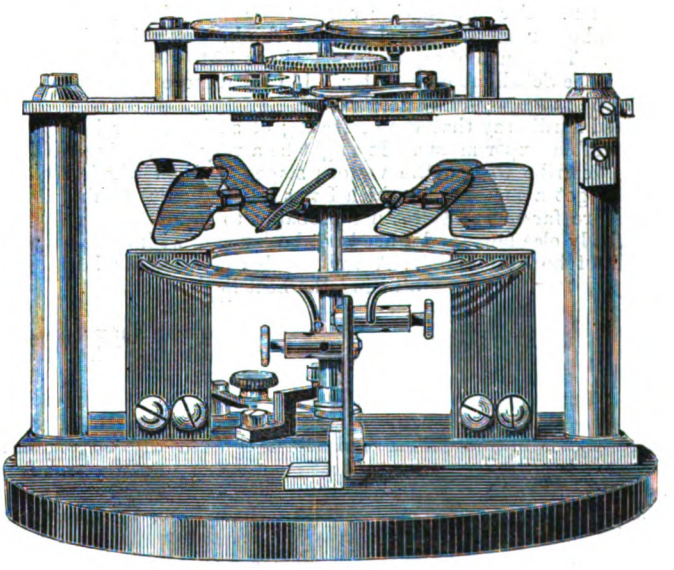

Fig. 8.

way of adopting it was the want of a meter for alternating currents. Such a thing did not exist, and I felt certain that the public would never be satisfied with a meter whose indications depended on the speed of reversals. In this I seem to have been a little in error; I believe the objection is not so serious as I then thought. It seemed to me that the heating quality of the currents was the only one which would succeed, and would be equally applicable to continuous aud alternating currents. I was fortunate enough to have the kind assistance of Mr. A. Stroh for perfecting the details of the instrument which I then set to work to make; and it is to Mr. Stroh's ingenuity and assistance in working out the details of the instrument that I almost entirely owe such success as the instru-

Digitized by Google

ment has attained. I cannot express too strongly the feeling of obligation which I am under to Mr. Stroh for his continuous assistance in developing this meter (applause). You may call this a "Windmill meter." I have several specimens on the table. The current is passing through one of them, which is now, as you see, rotating. The conductor in the meter carries the current, and is just underneath a kind of windmill. The conductor becomes heated, and sets up convection currents in the air; these convection currents turn the windmill, and the number of revolutions of this windmill are indicated by mechanism, much like those other mechanical meters which I have shown, and the total velocity is proportional to the current.

The windmill which I use is made of a horizontal mica disc, with mica vanes round the edge, inclined at 45deg., attached to it by small pieces of pith. It has a hole in the centre, in which is fitted a thin paper cone, which has at its apex an aluminium cone, supporting a steel pinion with a ruby cup in its centre. This cup rests on a needle point, and the pinion works into the train of wheels which does the counting.

When this meter was perfected it seemed that the English demand was not great, and it was best to modify it to suit the American market. I went to America to find out exactly what was wanted, and altered the instrument accordingly. The chief objection raised to it was the difficulty of mailing it, and a fear that it was too delicate. Consequently I strengthened some of the parts, reduced the sharpness of the needle point, and provided a metallic case in place of a glass shade. A considerable number have been sent across the Atlantic in both directions without any injury by the ordinary channels. On arrival all that has to be done is to loosen a screw, so as to free the windmill, and let it play upon the needle point. The electric resistance of the conductor had also been objected to. That was a serious objection to the instrument as it was first brought out, though I did not notice it until I began actually to have it in practice on lamp circuits. This I was able to correct by altering the form of the conductor in which the heat is produced. Its resistance is now $\frac{1}{100}$th of an ohm, and Mr. Schallenberger, after testing at Pittsburg a batch which were sent direct from Mr. Grove's workshop, without any adjustment, wrote to me, saying that they are quite accurate, and that the fall of voltage, due to resistance, is quite low enough for practical purposes, and that they were put to work on the regular commercial circuits in Pittsburg. Mr. Westinghouse has acquired the rights for America, and is now manufacturing them at Pittsburg. It is the only meter which he supplies for motors and continuous currents, and it also works equally well with alternating currents of any speed of alternation. For alternating currents he has hitherto used the Schallenberger meter, and I should think, probably, will do so largely. The range of my meter is about 12 to 15-fold, about the same as the Schallenberger meter. If I used more delicate wheelwork, the range would be greater.

I need hardly say that the perfecting of such a meter has led to innumerable experiments. It might be a very interesting task to me to describe to you the various stages through which I went before I got a meter with which I was satisfied; but I think these details are far more interesting probably to myself than they are to anybody else here, and I need not bother you with these varying periods of hope and trial. A vast number of attempts have been made at other means of utilising the heat in the best way. I will not describe these various methods, which did not generally arrive at much success, but I feel that I would not be doing my audience justice if I did not show them one other type which I have constructed, which is very simple and effective, but which has one slight defect—viz., that it is not easy to manufacture in numbers, all exactly alike. This meter consists of a wire conductor of very low resistance indeed. This conductor is covered with cotton, and is kept moistened by having the cotton dipping into a vessel full of alcohol. The heat generated in the copper wire evaporates the alcohol on the cotton, and deposits it in a tube, in which the quantity of alcohol condensed may be measured. This is very accurate over a considerable range; but it is very difficult to make a large number of them to read the same. This instrument has not been used on commercial circuits, and therefore in accordance with the dictum with which I began this address, I ought not to have alluded to it; but I felt that I ought to say this for other reasons.

Since the beginning of September, 1887, when I first exhibited the mill-wheel meter, an enormous number of patents for meters have been taken out; indeed, the weekly patent return almost invariably shows a new meter taken out every week. But I think I have described (at any rate I have done my best to find out and describe) to you all those which have as yet proved themselves to be of practical value. Each of the meters I have described has its merits, and all are doing good work in central station distribution in some part of the world or other (loud applause).

An interesting discussion followed, which will be given in our next issue.

THE WEST BROMPTON STATION OF THE HOUSE-TO-HOUSE COMPANY.

(Concluded from page 368.)

Switch and Test Room.—All the electrical connections converge in the switch and test room, and the man in charge there can control by signals the starting or stopping of any set of plant and the connecting or disconnecting of any circuit. The high-tension terminals of the dynamos are hidden in the frame, and the wires are taken by a covered main trench to the switch room. This trench runs all around the switch room behind a screen. The switch blocks are mounted on this screen, and the connections made behind, so that not a single wire or connection is in the room.

The leads are first brought to a double-pole cut out, arranged so that a fuse can be replaced without stopping the dynamo; and by a system of four break switches, which will be explained later on, any dynamo can be put in communication with any circuit or circuits, or the whole of the dynamos can be put in parallel circuit. Besides these mains conveying the entire E.M.F. of the dynamo, a small wire is brought to the switch-room, and placed across one coil of the armature; this is for measuring the voltage, synchronising, and for regulating the E.M.F. Each coil being exactly similar, the measure of one coil is a direct proportion of the whole; this device obviates any inaccuracies that would occur in measuring from a converter. A simple current register is also included on the switch board to indicate to the attendant approximately the current given out by each dynamo, and is arranged to ring a bell when the maximum safe load of any dynamo is reached, when he can either put in another machine parallel or put one of the circuits on some lighter working dynamo, if working independently. The synchronising is effected through the one-coil circuit; for instance, if one machine shows by the indicator that the load is approaching the normal, and another plant is started, a small switch places the second machine parallel with the first machine, though one lamp only, placed on the synchronising board. When the phases of the two dynamos correspond the lamp is steady and bright, but not until then. The second machine is then instantly put in parallel with the first by the insertion of one main switch, and at once takes half the load. Any inclination of one plant to get out of pulse with the other throws more of the work on the faster engine, and reduces its speed, so that one plant controls the other. The regulation is also done from the single coil circuit, a small converter being interposed between it and the regulator to insure the attendant from any shocks that might accrue from a fault in the circuits or dynamos.

The E.M.F. Regulator.—The method of regulation adopted in the Lowrie-Hall depends upon the thermal effect of the current. A wire rigidly attached at its extremities and weighted at the centre is connected to the terminals of the dynamo, and the sag formed in the wire by the central weight, when the wire is expanded by the heat generated, gives an efficient and sensitive motion which is well adapted to the purpose in view. For an example, if the wire be 60in. long, and its expansion is one-quarter of an inch, then the sag of the wire amounts to 2·74in., which is equivalent to a gear multiplying eleven times, with none of the friction or other cause of loss of sensibility appertaining thereto.

Fig. 2 illustrates the complete instrument. Fig. 3 is a diagram of the connections.

Across the terminals of the converter M, two fine wires, E and F, supported between the fixed points, Z, Y, and Z^1, Y^1, whose normal positions when cold are shown by the dotted lines, are connected; the two wires being in series with one another, and connected by the wire, Y, Y^1. The field-magnets of the dynamo A are excited by the exciter B. Across the fields of this exciter a shunt of varying resistance is placed, connected by the wires, d, d^1; this shunt resistance is formed by two metal plates dipping in the solution in the electrolytic cell D, and its resistance is altered by the raising and lowering of the plates into the solution, which is accomplished automatically by the passage of a current through either the top coil C, which

Digitized by Google

lowers them, or the bottom coil C^1, which raises them by their attraction for a movable iron core inside the coils. This core is attached to the plates by a cord passing over a pulley, d^2.

To the centre of the wire E a cord is attached, the other end of which is fixed to the arm e of the rocking arm e, e^1; this arm is pivoted at e^2 on a fixed support. If the E.M.F. of the dynamo rises too high, the sag becomes greater, and the arm e is pulled down by the weight e^3, and so makes contact on the table c; if, however, the E.M.F. falls, the wire pulls the arm e up, so causing the other arm e^1 to make contact with the table c^1. To the centre of the wire F the cord f is attached, which raises or lowers the arm f^1, pivoted at its end, off or on to the table f^3. This table, f^3, is connected to one pole of the exciter, and the pivot of the arm f^1 is connected by the wire f^2 to the pivot of the rocking arm e^2; the able c is connected to the top coil C, and the table c^1 to the bottom coil C^1, the other ends of these two coils being jointly connected to the other pole of the exciter.

If now the E.M.F. of the dynamo rises too high, the arm e falls, so making contact with the table c; the E.M.F. of the exciter is therefore right across the coil C, one side being in metallic connection, and the other being connected through the table f^3, up the arm f^1, through the wire f^2, to arm e, so passing through the table c, connected with the coil C. This coil coming into action pulls the core up and so lowers the plates into the solution, which therefore lowers the resistance of the shunt, so causing a smaller current to pass round the fields of the exciter, and consequently weakening the field of the dynamo A, so lowering its E.M.F. These coils are wound with fine wire, and are of high resistance.

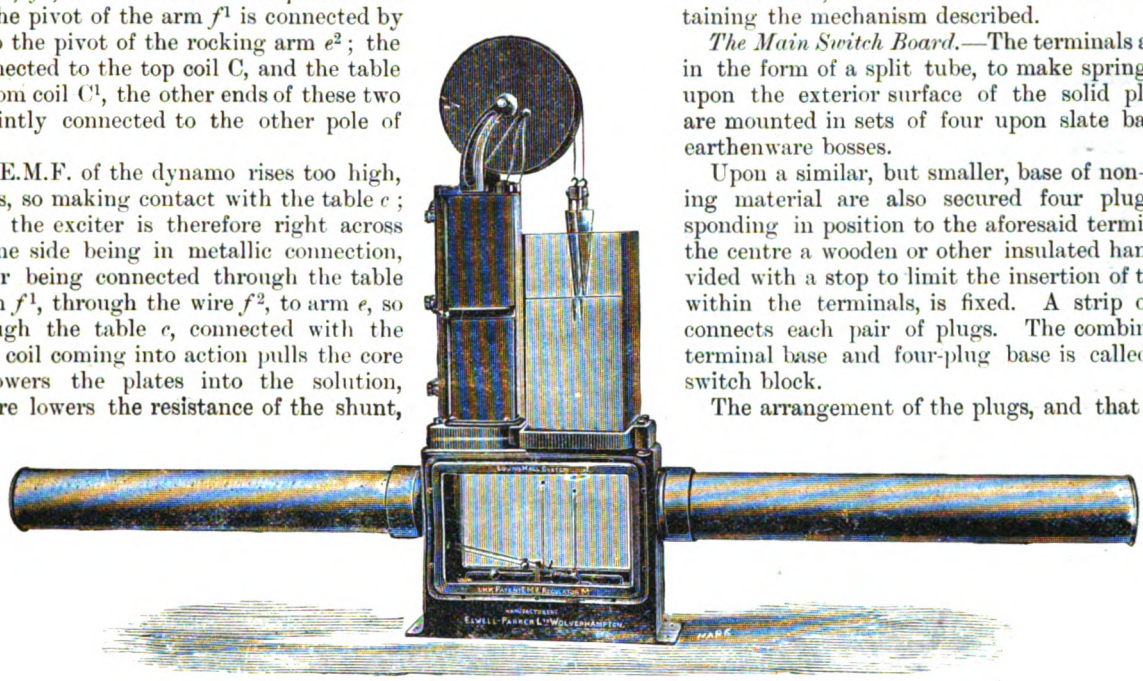

FIG. 2.—THE LOWRIE-HALL POTENTIAL REGULATOR.

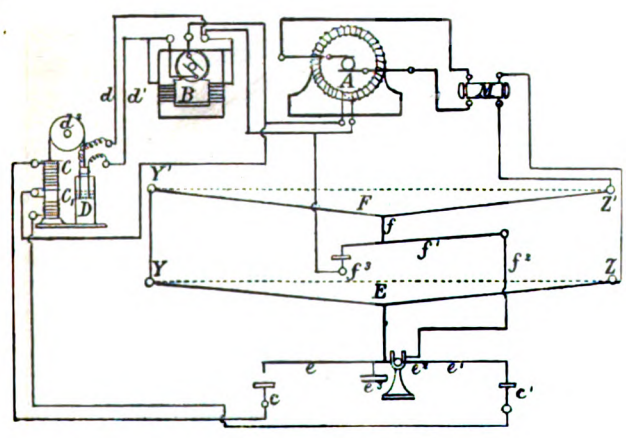

FIG. 3.

If, however, the E.M.F. is too low, the arm e^1 touches the table c^1, so shunting the current through the coil c^1, which coming into action raises the plates out of the solution, and consequently the resistance of the shunt, so that more current passes from the exciter round the fields of the dynamo A, whose E.M.F. therefore rises. The arm f^1 is put in to cut out the action of the regulator in the event of the wire E breaking, for that wire by breaking would stop the passage of the current through the wire F, so making the latter contract and pull up the arm f^1, so breaking its connection with the table f^3. If no provision is made for this accident the arm e, by making permanent contact with the table c, would lower the E.M.F. of the dynamo as far as the shunt would allow. In the shunt resistance the two plates which are fixed to an insulating piece dip into the solution contained in the glass cell, and are supported by two chains, which pass over the two ebonite wheels. On a smaller pulley a chain is fixed, supporting the iron core, which moves up or down in the coils; the speed of the motion of the plates is increased or decreased by the ratio of the diameters of the pulleys. The coils are wound upon a brass tube, which is filled with glycerine to act as a dashpot, the core acting as a plunger itself.

In the actual instrument (Fig. 2) the wires are stretched in a brass tube, in the centre of which is a box containing the mechanism described.

The Main Switch Board.—The terminals are made in the form of a split tube, to make spring contact upon the exterior surface of the solid plugs, and are mounted in sets of four upon slate bases with earthenware bosses.

Upon a similar, but smaller, base of non-conducting material are also secured four plugs corresponding in position to the aforesaid terminals. In the centre a wooden or other insulated handle, provided with a stop to limit the insertion of the plugs within the terminals, is fixed. A strip of copper connects each pair of plugs. The combined four-terminal base and four-plug base is called a unit switch block.

The arrangement of the plugs, and that of their corresponding terminals, is that of a rectangle, nearly square in dimensions. This is to prevent the plug base being inserted wrongly in the terminal base, that is to say, to make vertical connections (for example) instead of horizontal ones.

Upon one side of each square is connected a generator, and upon a horizontal line with each of these are the terminals of the outer circuits.

The arrangement is such that one pole of a dynamo machine is connected to one terminal of a unit switch block, while the other pole is connected to the diagonally-placed terminal of the same switch block. Similarly, each pole of the outer circuit switches is electrically connected to the remaining two terminals of the same block.

Provision is made by grooves at the back of each unit switch-block to extend all the electrical connections to the adjoining unit blocks in the same symmetrical manner. For example, when four unit blocks are combined together as a square, with connections from two dynamos on one side, and connections to two working circuits at right angles thereto, the whole of the current from the two generators can be conducted into one of the working circuits; or the current from one machine led into one circuit while the other machine is supplying the other circuit; or one circuit is fed by both machines while the other circuit draws its supply from one machine only; or, finally, both circuits may be fed by both generators, according to the number and arrangement of the plug bases engaged with their respective terminal bases.

Thus any number of generators and circuits can be electrically connected by adding the requisite number of unit switch blocks in the manner indicated. For synchonising previous to connecting two dynamos in parallel an incandescent or glow lamp is provided beside the unit switch blocks.

Distributing Mains and Method of Testing.—After leaving the switch board, the different circuits are composed of very highly-insulated conductors, encased in lead and braided outside, all joints in which are made by a special machine. These mains will be drawn into cast-iron pipes, specially designed to overcome the objections of Local Authorities to disturbing the road after the pipes are once laid down. The road boxes, junction boxes, distributing boxes, &c., used in this system are all made interchangeable to any size pipe, either main or branch. A considerable length of piping has been laid down, but the conductors are not drawn in.

An ingenious method has been devised for testing the insulation while the current is on. The apparatus consists of a small box containing a vacuum tube, one of the electrodes of which is connected to earth, while the opposite electrode is connected by its terminal to a pole of the conductor under test. The box is provided with an orifice through which the tube may be observed, and the interior of the box is blackened. If the insulation of that portion of the conductor under test is bad, the characteristic glow of the vacuum tube when current is passing between the poles is wanting, because earth connection is made at the extremities of the testing circuit. On the other hand, if the insulation is good the glow of the tube is present, because current is discharging through the vacuum tube to earth. The glow is vivid or otherwise in proportion to the quality of the insulation and potential of the current, and may be compared with a standard vacuum tube or other light-giving means, and measured by a photometer.

Each pole of the insulated conductor is tested in the manner indicated above, as it is to be noted that if a fault exists upon another portion of the conductor than that under test (the latter being well insulated) the glow is present; but on the connection being shifted to the opposite pole—on the faulty side of the cable—the discharge through the tube is diminished or ceases in the manner before stated. Any section of a conducting cable may be tested, and a fault localised in the manner described. The use of this continuous recorder entirely removes the necessity of stopping any circuit unless a fault is known to exist, and the risk of inconvenience by stoppage of the light is reduced to a minimum.

The Lowrie-Hall transformer was described in our issue of February 10th, 1888, p. 343. The Lowrie-Hall meter is described and illustrated in the present issue by Prof. Forbes in his recent lecture before the Society of Arts.

UNDERGROUND MAINS.

BOARD OF TRADE CIRCULAR.

We are indebted to the Secretary of the Board of Trade for the following copy of a circular which has been addressed to various local authorities in whose districts roads have been broken up for the purpose of laying mains for electric lighting purposes:—

(Copy.)

"Board of Trade (Railway Department), London, S.W.
"29th January, 1889.

"SIR: I am desired by the Board of Trade to state, for the information of the Vestry, that their attention has been called to the fact that certain streets in the parish of ——— have been, and are being, broken up with a view to the laying of mains for the supply of electricity by persons having no statutory powers under the Electric Lighting Acts, 1882 and 1888.

"The Board of Trade have been advised that no member of the public (and a company not possessing statutory powers would be in the position of a member of the public) can either with or without the 'assent of the local authorities interfere with public highways in such a way as to cause obstruction to the public, even though such obstruction were limited to the time during which they were executing their work.'

'It is in the opinion of the Board of Trade very undesirable that mains for the supply of electricity should be laid down in any street, being a public highway, by persons possessing no Parliamentary powers.

"The applications for statutory powers now before the Board of Trade show that there is considerable competition in the metropolis for the privilege of supplying electricity, and the difficulty of dealing with these applications in the general interest of the public will be materially increased if individuals or companies have laid mains without statutory powers and consequently without the obligations which the Legislature has imposed for the protection of the interests of the public.

"It must also be remembered that the financial interests of electric undertakings which occupy streets with their mains, and supply electricity to the public without statutory power, are by no means secured in the same way and to the same extent as if they possessed those powers, since, in the first place, their works run the risk of being stopped by the direction of a court of law at the instance either of some public authority or of any one who may at any time now or hereafter feel himself aggrieved; and since, in the next place, they do not possess the remedies for enforcing against their customers their charges which the Legislature has given to those who obtain statutory powers.

"The status of applicants to the Board of Trade, and through them to Parliament, should be such as to ensure perfect equality to all, and there is danger that this might not be the case if any persons either being or about to be applicants for statutory powers were in the actual occupation of streets.

"It has become, therefore, necessary to consider the action which may have to be taken in view of the facts above referred to, and I am desired to request the early observations of the Vestry upon the points mentioned.—I am, sir, your obedient servant, (Signed) "HENRY G. CALCRAFT."

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714.

All Communications to be addressed to "The Electrician," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician."

All letters intended for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.

"The Electrician" is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.

SPECIAL NOTICE.

Owing to the increase in the number of pages of "The Electrician," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
„ Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"The Electrician" offers exceptional advantages to Advertisers. **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Trade Advertisements *intended for the current issue must be handed in not later than First Post on Thursday morning.*

Small Prepaid Advertisements *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"The Electrician" Printing and Publishing Company (Limited) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "The Electrician" Electrical Trades' Directory and Handbook. *The Directory was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY.

CONTENTS OF THE CURRENT NUMBER.

Notes	387	Books Received	409
Notes on Electro-Magnetic Induction. By Dr. J. A. Fleming, M.A. Illustrated. Continued	392	American Notes	410
Electric Meters for Central Stations. Illustrated. Continued	393	Notes from Germany	411
The West Brompton Station of the House-to-House Electric Company. Illustrated. Concluded	396	Scandinavian Notes	412
Underground Mains.—Board of Trade Circular	399	Correspondence—	
Meetings of Scientific Societies.	399	Inductive Influence between Distant Circuits.—Oliver Heaviside	412
The Kensington Vestry and the Electric Light	400	Light Without Heat.—A. B. Worth	412

THE KENSINGTON VESTRY AND THE ELECTRIC LIGHT.

As the parish of St. Mary Abbotts, Kensington, comprises one of the wealthiest residential districts of the metropolis, and is consequently one of the most promising areas for the introduction of the electric light, it is not surprising that it should have occupied a prominent position in the minds of nearly every electricity supply company in London, or that the parish itself is very much alive to the value of the patronage which it has to bestow. It remains to be seen whether any of the rival companies will push their claims to the verge of self-destruction by conceding too much; but on the part of the parish authorities it is plain to be seen that they are not disposed to let the applicants concede too little. Evidence of this will be found abundantly in the elaborate Report of the Electric Lighting Committee appointed by the Vestry, an abstract of which we publish in this week's issue. The Report itself is of great interest just now, partly because of the importance of the district to which it relates, partly because of its being almost the first of its kind yet published, but partly also because of the evident care and ability which have been devoted to its consideration. The Kensington Vestry have lost no time in adopting the Committee's Report unanimously; and it will probably be taken as a model and a precedent for other

Digitized by Google

vestries to copy and to follow. This being the case, a great responsibility rests upon the electric lighting undertakers for the Kensington district to see not only that their own interests are equitably dealt with, but that those of the trade generally may not be handicapped by concessions which in other less favoured localities may be utterly inadmissible.

We shall, in fact, be surprised and disappointed if certain of the conditions proposed in the report are accepted by any of the competing companies; but at the same time we have no serious fault to find with the committee for endeavouring to make a good bargain where the opportunity, as in this case, is so tempting. And in many respects the Report is characterised by a fairness and reasonableness which are highly praiseworthy. Beginning by careful inquiry into the financial position of the six applicants for Provisional Orders in the district, the Committee have decided that none of the companies shall be excluded on that ground, but that on grounds of expediency affecting all the parties concerned, separate and independent areas shall be assigned, in the first instance, to each company. Its undisturbed possession will thus depend upon its efficiency and good behaviour, a condition which is further safeguarded by the suggestion that a larger area than that comprised in the Order shall be provisionally assigned to each of the companies, such extension of area to overlap the territory assigned to one of the others, so as to create what the Report felicitously calls a "potential competition" in case it is ever required. As the Act does not in any case confer exclusive rights, such as are possessed by gas and water companies, the plan approved by the Kensington Vestry is perhaps as near an approach to a monopoly as the electric companies can hope to obtain. With regard to the assignment of the several areas there will probably be some heartburnings and disappointments. All we need say on the subject is, that in examining and reporting upon the merits of the several claimants the Committee appear to have done their best to arrive at a sound decision, and have given their reasons for it frankly and fairly, though possibly in one or two instances with insufficient knowledge.

On the question of charges, too, the Committee cannot be blamed for adopting a suggestion which has actually been put into their heads by one of the competing companies, namely, that of a sliding scale such as prevails with the gas companies. A difficulty is foreseen in the case of electric supply, which is a new industry, seeing that no one can accurately estimate beforehand or ascertain afterwards the amount of capital properly and necessarily spent on the undertaking. Perhaps it is this uncertainty on which the House-to-House Company reckons in offering to diminish or increase the standard price, subject to a decrease or increase in the standard rate of dividend (10 per cent.) Has the House-to-House Company forgotten, when thus putting itself on the same footing with the gas companies in respect to prices, that it is on a totally different footing in respect to tenure? The older supply corporations have a permanent monopoly, whilst the new corporations which are now being created have rights only—and those not exclusive—for a limited period of at most forty-two years—a period the authorities desire to cut down even still further. There is nothing essentially unfair in the Vestry accepting these terms; but by accepting them in detail, as proffered by the House-to-House Company, the Kensington companies may be not only doing a wrong to themselves but to their brethren who are seeking Provisional Orders elsewhere.

On the subject of overhead wires the Vestry appear to have been influenced by panic. Without a vestige of evidence one way or the other they recommend that no company shall be at liberty to carry wires otherwise than underground, and that all existing overhead wires be removed on the Provisional Order taking effect. In a note we are told that all the undertaking companies practically agree to this requirement, and reference is made to their answers to questions tabulated in an appendix. Turning to page 22, we find that the answers, where any are needed, are rather conditional than positive, one of them being "Overhead wires will be removed as soon as underground mains system overtakes them." If the Vestry are satisfied with this answer, so are we; indeed, it is the most rational answer that can be given in the circumstances; and as it is not very likely the Vestry will use their powers, even if obtained, of constructing "culverts and channels to hold electric mains," the companies may safely be left, in this particular, to the mercies of the Board of Trade.

With regard to the Purchase clause we very much regret to find, from a statement towards the end of the Report, that the Vestry has not only set its mind upon reducing the period from forty-two to twenty-one years, but that it is not unlikely to carry its point. The Report states that the Committee have reason to believe that "all the companies would consent" to this curtailment. If this is the case we must again exonerate the Vestry from blame in the matter; but it is almost past belief that the very people who protested against the twenty-one years' limitation of 1882 should now deliberately abandon the concession of forty-two years obtained in 1888—a concession for which they had been stenuously fighting for six years past, and without which they were said to be unable to undertake any business at all. We shall be greatly astonished if these electric lighting companies have stultified themselves in this cynical fashion; and we should imagine that the profession and trade of electrical engineering throughout the whole country will indignantly refuse to accept it as a precedent for their own action outside the Parish of St. Mary Abbotts, Kensington. Similar conditions, it will be seen, have been introduced by the Committee on the lighting of the City area, whose Report also we summarise and print this week.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

Section III.—Magnetic Fields of Coils and Solenoids.

(*Continued from page 335.*)

144. *Direction of Magnetic Field in the Region of a Circular Current.*—Only a few months back the attention of the scientific world was directed once more to the life and labours of that great French mathematician and physicist, André Marie Ampère, the occasion being the unveiling of a statue in his memory erected by his fellow citizens in the city of Lyons. Immediately upon the news reaching Paris of Œrsted's discovery of the action of a current of electricity upon a magnetic needle towards the close of 1820, Ampère keenly followed up the subject, and very soon after gave to the world his electrodynamic theory, embracing the laws governing the mutual action between conductors carrying currents of electricity, based upon which we now have some remarkable current and electricity meters. Among these may be cited Siemens' electro-dynamometer, in which a current circulating in two coils, one fixed and the other movable, is measured by the amount of mechanical force required to counteract their mutual attraction. Or, again, the Ferranti meter, in which the current to be measured passes radially through a mercury bath, and then through a fixed coil outside it, causing rotation of the mercury, and setting in motion a train of clockwork indicating the quantity of electricity passed

Digitized by Google

through the meter in a given time, and more recently the beautiful ampere balances of Sir William Thomson, in which the movable coils are at each end of a balance arm, and are attracted, one up and the other down, by a pair of fixed rings, embracing each movable coil. In this instrument a sliding weight is moved along the bar until a position is found, such that the balance arm is restored to equilibrium, and this position indicates on a scale the strength of current passing through the coils. Measuring instruments such as these, designed on the principle of the attraction between fixed and movable portions of an electric circuit, have the invaluable property of being capable of measuring the strength of currents *alternating* in direction as well as direct currents.

But, further, Ampère gave a precise explanation and theory of the magnetic character of electrical circuits; in fact, he showed that when a conductor carrying an electric current is bent into the form of a single ring or a series of rings side by side, such as a spirally-wound coil, that the behaviour of such is identical with the behaviour of a magnet. The spirally-wound coil, in which a current is circulating, acts, as regards attraction, repulsion, and external magnetic effects, exactly like a cylindrical bar magnet, presenting, as it does, at its extremities north and south magnetic poles. Similarly, a ring-shaped coil, through which a current circulates, presents opposite magnetic poles at its two faces, being, in fact, identical in magnetic effect to a thin slice off a cylindrical bar magnet. Such a thin slice or disc of magnetised iron is called a *magnetic shell*, and the ring-shaped coil carrying a current which is equal in magnetic action to such a shell is termed its *equivalent* magnetic shell. Further, every plane closed circuit of whatever external shape can be shown to have its equivalent magnetic shell.

It is with this part of the subject that we have now more particularly to deal, and to make the subject as easily understood as possible we shall first consider only the *direction* of the magnetic field in the neighbourhood of a circular current, and then show how its exact value at different points may be determined by Ampère's laws. Suppose, first, a portion of a conductor carrying a current, bent into a ring as in Fig. 128, the

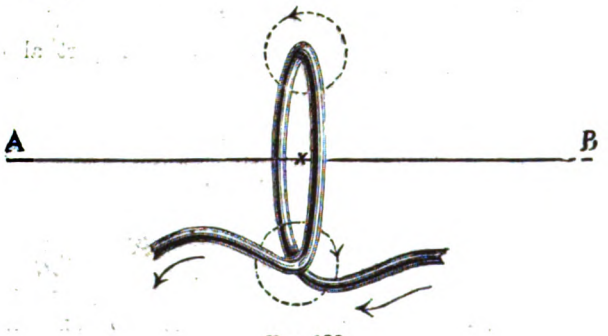

Fig. 128

arrows representing the direction of the current. Now what is most useful to know with reference to the action of galvanometer coils is the direction and magnitude of the magnetic field along what is called the axis of the coil. The axis of a coil is an imaginary line in the same position with regard to a coil as a shaft is in with regard to a pulley keyed to it—that is, it is a line (such as the line A B in the figure) whose direction is at right angles to the plane of the coil, and which passes through its centre. Lines of force will enclose the conductor in circles at every point throughout its length. Now let us consider separately for a moment those circles of force which lie in the same vertical sectional plane of the ring, one at the top and the other at the bottom, and let us examine the magnetic field they create along the axis A B. Having found this we can add up the fields set up by every sectional plane of the ring, for every one of these planes acts alike. The direction of the circles of force will be understood to be as indicated in the figure, because the current is flowing *towards* us in the top of the ring, and *away* from us in the lower portion. Take, first, the action of the upper portion of the ring and let us consider it separately, the section of the wire being represented at W (Fig. 129). On the axis A B let us mark out a series of points (1 at the centre and 2, 3, 4 on each side of it) at which to determine the field set up. Circles of force emanating from the conductor W as centre will pass through all these points. Now we have already stated that when a force acts along a circle, its direction at any given point is at a tangent to the circle. We have familiar examples of this tangential action in centrifugal separators. For example, if the dotted circle in Fig. 130 repre-

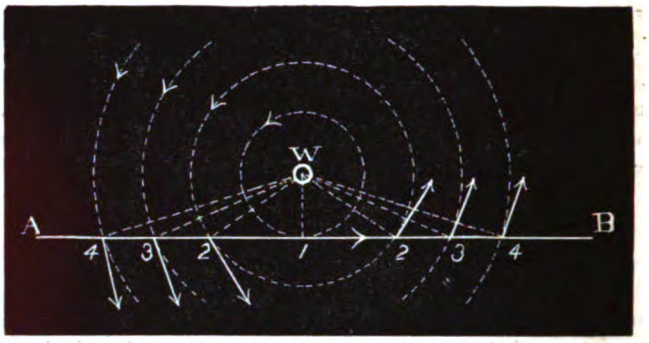

Fig. 129.

sents a body revolving in the direction shown, the forces acting at any moment when it passes the points A B, C D, are tangential to the circle, or at right angles to the radii at those points, and this is the case for *any* point we may take on the

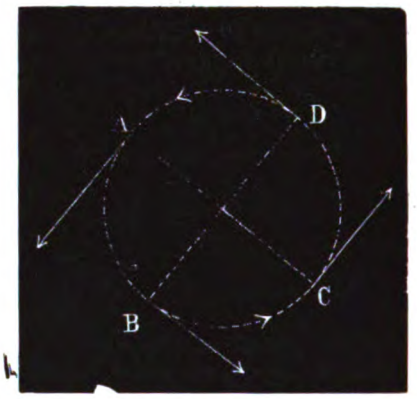

Fig. 130

circle. Applying this principle to the circles of force round the conductor, we find the *direction* of the magnetic forces by drawing lines at *right angles* to the radii of the circles passing through the various points, and assigning to them a direction agreeing with the direction of the circles of force. It will be noticed, then, at the point 1, which is at the centre of the ring, the direction of force is along the axis of the ring, but as we get further away from the plane of the ring the forces become more and more nearly at right angles to the axis. Now,

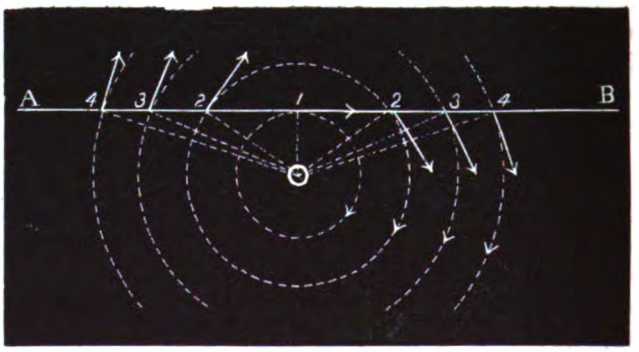

Fig. 131

consider the action of the circles of force emanating from the lower portion of the ring. Fig. 131 represents this action, where 1, 2, 3, 4 are the same points as chosen above, and the circles of force are in the opposite direction. Proceeding in

Digitized by Google

the same way, we find that at the point 1 (the centre of the ring) the force acts along the axis of the coil *in the same direction* as the force due to the upper portion of the ring, and the forces at the other points act at the same angles relatively to the axis as those above. Now combine the two sets of forces by setting them out together along the axis (Fig. 132), the upper and lower sections of the conductor composing the ring being indicated at W W. Here we find that although the forces diverge more and more from the axis as we proceed further away from the plane of the coil, yet each pair of forces has its *resultant along the axis*, and all resultants are in the same direction as the two forces at the centre due to both portions of the conductor. Further, the resultants of these pairs of forces become less and less as we take them further from the plane of the

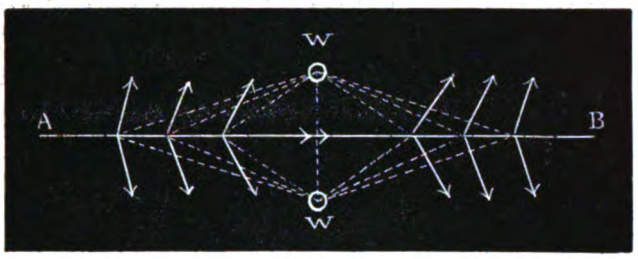

FIG. 132.

coil, because the forces themselves act more and more in a direction *opposing* each other, and therefore tend to reduce the intensity of the resultant horizontal forces.

(To be continued.)

"NOTES ON THE DESIGN OF ELECTRIC MOTORS."

On Wednesday, the 30th ult., at the City and Guilds of London Institute Old Students' Association, the following discussion took place upon Mr. Albion T. Snell's Paper read to the Association on the 16th ult. (See *Electrician*, January 18th.) The President (Mr. Thomas Adams) occupied the chair.

DISCUSSION.

Mr. W. B. ESSON*: Taking the principle of reversibility, Mr. Snell of course finds that for a series motor there is no critical current—that is, any current above that required to overcome its friction will make it run. But for a dynamo a current lower than a certain value, called the critical current, is impossible. From this Mr. Snell seems to think that there is something radically wrong in the principle of reversibility, but I think this is a mistake. I made some experiments years ago to ascertain the effects of the reactions of the armature on the field, and concluded that in any machine run both as dynamo and motor with similar currents the effects as regards the weakening of the field were exactly similar. The case stands thus: Take a series machine and send a certain current through the field-magnets and armature. There is undoubtedly a delay in magnetisation, as pointed out by Ayrton and Perry some years ago, but I do not attach importance to this effect in continuous-current machines. Although negligible in these, in alternate machines, however, the magnetic delay becomes enormously important. Well, neglecting this delay, let us send, in both motor and dynamo, the same current through the magnets and armature; it stands to reason that the fields being identical whichever way the armature turns the reaction must be exactly the same, provided that the back lead in the motor is equal to the forward lead in the dynamo. In a motor the only difference is that the armature runs round the other way, the magnetisation of the system and distribution of the field being the same in both cases. In the experiments mentioned, a dynamo was taken with a Gramme ring core saturated to a fairly high degree. This was run to produce several different currents. As a motor it was run at the same speed, and braked until the same currents flowed as were generated when it ran as a dynamo. With the current flowing in the same direction through the machine, the armature revolved, of course, in the opposite direction, the brushes having the tips rounded so that their ends did not turn up with the reversal. If V_1 and V_2 are the differences of potential at the terminals of the dynamo and motor, then I found in each case that—

$$V_1 + C R = V_2 - C R,$$

where C was the current and R the resistance of the machine. I concluded from this that the reactions were in both cases similar, and that the delay in the magnetisation of the armature core was also inappreciable.

* Mr. Esson's speech was delivered at the first meeting after the reading of the Paper.

Now we come to the self-induction. In this direction I have been making several experiments lately, and find that in armature cores saturated to 16,000 or 18,000 C.-G.-S. the effect of self-induction may be entirely neglected. The experiments are made thus: The machine is separately excited, and run without any lead on open circuit, the E.M.F. and speed being noted, also the ampere-turns on the field. We now let a current flow through the machine, and note the increase of excitement required to bring the E.M.F. to its previous value—that is to say, the difference of potential at the brushes when running at the same speed is equal to its previous value *minus* the current into the resistance of the armature. There is no lead to the brushes, and therefore any weakening of the field is due to self-induction; and I find that at 16,000 or 18,000 C.-G.-S. the number of turns required to bring the potential when the current flows up to its former value is inappreciable, while at lower degrees of saturation a certain number of ampere-turns have to be added, which get larger as the saturation is reduced. To get $V_1 + C R = V_2 - C R$ the core must, of course, be well saturated, so that self-induction does not come into action.

Regarding the effect of the armature field on the main field, I disagree entirely with Mr. Snell. It is quite true that Ayrton and Perry showed that the effects due to both might be added if the motor were worked with a forward lead; but, if I recollect rightly, Ayrton and Perry stated that under usual conditions of work the brushes must have a negative lead. With this you must have a weakening of the field. You cannot have an increase; it is a physical impossibility. I might say that one of the reasons of a shunt motor governing so perfectly is due to this weakening effect on the field of the armature windings. As the current rises the field is weakened, and the effect is similar to that of a series coil wound on the magnets in the reverse direction to the shunt. For constant speed we require, therefore, no compound winding, but only a particular relation of field to armature. I have seen a shunt-motor in which the speed actually increased as the load was put on.

As to the ratio of field-magnet to armature cross-section, it is worthy of note that the cross-section of armature core can be varied very considerably without affecting to any considerable extent the number of lines of force through it. This arises from the fact that the ampere-turns required for the induction through the core is only a fraction of the ampere-turns on the whole machine. In investigating this my firm constructed two armatures—one had a cross-section equal to ·6 that of the magnets; the other was ·8. The windings were similar, and so was the length; in fact, the only difference was that the hole in the centre of the armature was in one of them smaller. Although the increase in the cross-section was very considerable, the maximum increase in induction due to similar excitements was in the core of larger section only from 5 to 6 per cent. The gain is therefore so small for considerable increase in weight that I think it is scarcely worth while making two types. For "useful" lines induced by the current in the armature core Mr. Snell ought to substitute "useless" so far as adding to the E.M.F. is concerned, for, as I have already shown, the field is always weakened by them, not strengthened.

I may say that it is a very difficult thing to calculate the magnetic leakage before the machine is built, but it is very simple to measure the leakage afterwards, and from that it is tolerably easy to deduce the leakage in other machines, both of the same and modified types. One point is worthy of remark. Taking the single horseshoe magnet, suppose that in such a machine the ratio of the total lines of force induced in the magnet limbs to those passing through the armature core is 1·32. Now, imagine that you make a mistake in your calculation before the machine is made by assuming the ratio at 1·2, instead of 1·32. The error in the assumed leakage is about 10 per cent., but the difference in the E.M.F. of the machine due to having made this error, and deduced the ampere turns accordingly, will only be about 2 per cent. The reason of this is that the number of ampere-turns required for the induction in the magnets themselves is fractional as compared with that required for the whole machine.

If the terminal difference of potential = V is the same when the machine is driven as both dynamo and motor, the respective speeds for similar currents will be in the ratio $V + C R : V - C R$, the dynamo, of course, being always the higher. I may mention that the electrical efficiency of a motor is always greater than that of a dynamo at the same speed and current, the efficiencies standing in the ratio of $\frac{E}{E + C R} : \frac{E - C R}{E}$, where E is the E.M.F. generated in each case. Of course it makes no difference to the E.M.F. whether the armature is belt-driven or current-driven, provided the fields are in each case the same.

One of the chief reasons for the ampere-turns having to be increased over that shown by the calculation is because in the calculation the demagnetising effect of the armature upon the field-magnets is neglected. This weakening effect is due to the lead of the brushes. In the Manchester machine, for instance, Dr. E. Hopkinson tells me that there are as many ampere-turns of series as of shunt wire, and the chief use of the series wire is to compensate the weakening effect produced by the current flowing through the armature.

Mr. Snell says, referring to the method I use, that I neglect leakage and self-induction. As a matter of fact, I neglect nothing, or rather I only neglect those things that are negligible. Self-induction is negligible, and the leakage I take always at one fixed ratio, an error in this producing, as I have shown, very small effect on the output of the machine.

In conclusion, I again express my regret at the absence of the author. Though my remarks have been of a somewhat critical character, it will be understood, I hope, that concerning most of the points of which I have not spoken I have only to utter unqualified praise. I have called attention only to those points to which I in some degree take exception.

Prof. AYRTON described the Paper as a very practical Paper by a very practical man. Such a contribution from one of the old students not only did great credit to the Association, but was of real value to the profession.

Digitized by Google

Mr. Snell's labours for the past few years in Mr. Immisch's factory had so thoroughly borne out the view that was put forward some seven years ago by Prof. Perry and himself as to the difference that ought to be borne in mind as to the construction of a good dynamo and a good motor, that he did not think they were likely to quarrel upon side issues. In 1882, when Prof. Perry and himself put forward this idea that the motor and the dynamo should be constructed in a different way, they were regarded as rather revolutionary seceders from the orthodox camp, and he did not suppose (in fact, he felt sure of it) that they had yet been received back quite with favour among the orthodox. It was, therefore, a matter of great pleasure to them to find from Mr. Snell's work that henceforth heterodoxy must be regarded as orthodox (applause). Mr. Esson's remarks at the previous meeting were of extreme value, because they came from another practical man (hear, hear). The work that practical men were doing, the fact of their being able, somehow or other, to find time in the exigencies of commerce and the drive of business to make scientific experiments, filled him with the utmost admiration. If he made any remarks which appeared to savour of a critical character, it must be understood that, so far from being hostile, his criticism would merely be suggestions thrown out for the purpose of enabling practice and theory to go hand in hand in the endeavour to obtain a really good motor, whatever might be the construction they were ultimately led to adopt. The results of the experiments made by Mr. Esson were a little staggering. Their effect was that if a certain current were sent through a machine running at a certain speed, the electromotive force developed in that machine was the same whether it was working as a dynamo or as a motor. If that conclusion was universally true, then the whole theory that Prof. Perry and himself put forward in 1882 as to the action of the armature in a motor would be groundless. Before the end of the previous meeting he had been able to see where the fallacy in Mr. Esson's conclusions lay. Mr. Esson had been expermenting with dynamos used as motors, and not with motors used as dynamos, and the difference was a very important one (hear, hear). The armature of a good modern dynamo, as they all well knew, was wound with but a few convolutions of wire, and was a weak electro-magnet. Therefore, if Mr. Esson had succeeded in proving that the addition of a weak electro-magnet to a strong magnet—whether with a plus sign or a minus sign—induces but little change, that does not really add much to our information as to what happens in a motor. Immediately after the meeting he suggested to Mr. Mather that he should make the same experiments that Mr. Esson had, and that he should make them not with a dynamo but with a motor. An Immisch motor was selected for the experiments. Mr. Mather, one of his assistants, together with two of the students, Messrs. Drew and White, made exactly the experiments described by Mr. Esson—that is, they ran that motor both as a motor and as a dynamo. As a motor of course it was run by the current supplied, as a dynamo it had to be driven by an independent source of power. The current was maintained the same in the two cases, and the speed was maintained the same. Various currents, as a matter of fact, were used in the different experiments, but the same set of currents were used when the machine was run as a dynamo as when it was run as a motor. The result completely disproved Mr. Esson's statements, as the following table would show :—

Experiments with an Immisch Motor. Speed throughout 1,400 Revolutions per Minute.

Series A.—Armature turning WITH *the brushes.*

I.—Run as a motor.

Amperes.	Volts at terminals.	Volts used in armature.	E.M.F. developed in armature.
12	31	2·3	28·7
14·3	35·5	2·7	32·8
15·2	38·5	2·9	35·6

II.—Run as a dynamo.

12	20·5	2·3	22·8
14·3	24·4	2·7	27·1
15·2	26·9	2·9	29·8

Resistance of armature in experiments I. and II. was 0·189 ohm.

III.—Run as a motor.

12	30·2	2·5	27·7
14·3	35·8	3	32·8
15·2	38	3·2	35

IV.—Run as a dynamo.

12	20·5	2·5	22·3
14·3	23·5	3	26·5
15·2	26·5	3·2	29·7

Resistance of armature in III. and IV. was 0·287 ohm.

Series B.—Armature turning AGAINST *the brushes.*

V.—Run as a motor.

Amperes.	Volts at terminals.	Volts used in armature	E.M.F. developed in armature.
12	30·8	2·64	28·16
14·2	35·2	3·15	32·07
15·2	36·2	3·34	32·86

VI.—Run as a dynamo.

12	22·3	2·64	24·94
14·3	25·8	3·15	28·95
15·2	27·7	3·34	31·04

Resistance of armature in V. and VI. was 0·22 ohm.

If now we compare I., which is the most favourable when the machine was running as a motor with the brushes, with VI., which is the most favourable when the machine was running as a dynamo against the brushes, we have :

Amperes.	E.M.F. developed in armature of Motor.	Dynamo.	Difference in percentages of smaller.
12	28·7	24·94	15
14·3	32·8	28·95	13
15·2	35·6	31·04	15

This proves conclusively that there is a stronger field when the machine is used as a motor than when it is used as a dynamo.

These experiments also disposed of Mr. Esson's objection that self-induction was of no consequence. Mr. Esson mentioned two experiments in which he found that $V + C R = V_1 - C R$. He concluded, therefore, that the effect of self-induction might be neglected, and that the delay in the magnetisation of the armature in appreciable. Well, of course, that was disposed of in exactly the same way. Mr. Esson was dealing with an armature with a small number of convolutions, not with a motor which had many convolutions. With an armature having a small number of convolutions the self-induction, which depends on the square of the number of convolutions, is, of course, of very little consequence. But that did not apply to a motor. The addition of the armature field is a very distinct feature in the motor, and he believed the self-induction might also be of considerable importance.

In the beginning of Mr. Snell's Paper he said "It is now generally admitted that the effect of self-induction in the dynamo armature is to increase the lead, while in the motor it tends to diminish it." He did not know that he could quite agree with that statement. The effect of self-induction is twofold. It is, of course, to diminish the current which passes with a given potential difference and a given resistance. It also is to delay the current. It is a little difficult to say what is the resultant effect. The two effects would somewhat oppose one another. The effect of delaying the current, no doubt, is to shift the poles round, and therefore to increase the lead of the dynamo and to diminish the lead of the motor. For with a positive lead in a dynamo shifting the poles round will take the line of commutation farther from the neutral position, whereas with a negative lead in a motor the shifting of the poles will bring the line of commutation nearer to the neutral position. But if they took into account the weakening of the current due to self-induction—possibly, however, that was not what was intended—then he was not so sure that they could put it exactly in the same way. It was most important to remember, when speaking of self-induction, that there are always two effects—the weakening, and the retardation ; and they may or may not help or oppose one another. Mr. Snell goes on, "Mr. Mordey has pointed out that in the generator the effects of self-induction in the armature winding are opposed to those of the Foucault currents in the core ; but in the motor they tend to increase each other." There, again, it is a little complicated as to what is exactly understood to be the effect of self-induction. There is no doubt about this, that the Foucault currents in the core of an armature are in the same direction as the currents in the windings, and therefore whatever effect the currents in the winding may have in changing the lead or diminishing the field, whatever it may be, there will be the same sort of effect produced by the currents in the core ; and, therefore, there is no doubt whatever that with a dynamo the currents in the core tend to weaken the field as well as the currents in the windings. On the other hand, the currents in the core in a motor will also tend to weaken the field, whereas the currents in the armature increase the field, as the experiments of Mr. Mathers show. If, instead of saying "the effect of self-induction" Mr. Mordey had spoken of the effect of the currents in the core and the currents in the armature windings he would perfectly agree. Mr. Snell has pointed out that it is of value to short-circuit the coil of a motor when it passes under the brushes, and not good to short-circuit the coil of a dynamo armature when it passes the brushes. In the Immisch motor the coils when they pass the brushes are short-circuited ; and that is of distinct value for this reason, that when you short-circuit those coils you get a current in the coil which is opposed to the current in the armature itself, and, therefore, the shifting of the field due to the currents in the armature is balanced by the current to a certain extent in the short-circuited coil ; whereas in the dynamo both currents would be in the same direction. Practically, then, short-circuiting the coil in the amature of a motor enables you to keep the brushes in a fixed position, whereas if you short-circuit the coil in the armature of a dynamo it tends to make the lead increase more rapidly with increase of current in the armature. Now, of course, one of the great objects that has been aimed at in modern machines, dynamos and motors, is to enable you to have the brushes in a fixed position without sparking when the current in the armature is increased. That object is approached more nearly by short-circuiting the coils in the motor, and would be departed from by short-circuiting the coils in a dynamo. He would like to know why Mr. Snell said "the field strength has to be relatively greater as the size of the machine is increased." It would be very advantageous if in his reply he could point out why he had been led to that consideration. Of course he might have been led to it simply by commercial reasons, because the expense of making a large armature is naturally considerable. Theoretically he did not see why there should not be a relatively large armature for a large motor as well as for a small one. Mr. Snell spoke of the E.M.F. of the motor as being the B.H.P. divided by the current. Of course that is not the back E.M.F. of the motor. It is a kind of imaginary E.M.F. Then Mr. Snell took the E.M.F., which he put as equal to the potential difference of the terminals minus the current and the resistance plus L_m, while L_m is the value of the reactions of the motor armature. He did not know that they could subtract from the E.M.F. in that way and hope to get right results. It seemed to him that that

Digitized by Google

became rather complex, and would possibly lead them into difficulty. He was very glad to see that Mr. Snell had used the method that Prof. Perry and himself suggested in their original Paper for plotting out the results, namely—

$$\frac{E}{n}, \frac{e}{n}, \frac{\text{B.H.P. } 746}{n\,c}.$$

That method was no doubt an extremely good one for trying to find out the curves of a particular machine. He could not sit down without expressing the admiration which they must all feel for the labours of Mr. Snell (applause), for his kindness in bringing his Paper before them, and especially he might end by saying—as, indeed, he began—that any remarks that he had made, apparently of a critical nature, were merely made suggestively, and not in any hostile spirit.

Mr. RECKENZAUN said he had perused the Paper several times, in the hope of finding some points about which he might disagree; but he had been unable to find much fault with the practical part of the Paper. His own views, based on long experience, coincided with those expressed by Mr. Snell. The fact that there was a decided difference between the reaction of the armature, when the same machine is working as a motor or as a dynamo, dawned upon him at a very early period in those early days—in fact, when the Paper of Profs. Ayrton and Perry was published. He made that Paper a kind of text-book, upon which he had been working more or less ever since; he considered Mr. Snell's Paper an excellent supplement to it (applause). Some six years ago he used one of his small motors of 1½ horse-power capacity to work as a generator. He wanted to generate a current out of a very small dynamo. He found that the same machine when running as a dynamo required 60 per cent. more speed to produce the same E.M.F. That surprised him very much at the time. In order to ascertain whether this result was merely due to the design, he made tests with every kind of dynamo then at his disposal. In conjunction with Mr. Capito, he tried each machine as a motor, then as a generator, and compared the results Among these machines were some of Bürgin's, Siemens', and De Meritens'. Of these machines, the Bürgin had the heaviest field-magnets, and he thought that this would give, probably, the smallest differences in the results. It was a series machine. The results he obtained with the Bürgin machine were as follows:—Running it as a motor, he obtained 10·76 revolutions, 17·8 amperes, 116·2 volts at the terminals, 2·67 electrical horse-power, 2·15 B.H.P. Running it as a generator 10·86 revolutions (which was as near as he could get it to the other) 17·8 amperes, 84·5 volts, 1·6 electrical horse-power. Then he made another experiment, keeping the electromotive force and the current as constant as possible. These figures would show how the speed varied. When running as a motor it made 728 revolutions, 19·4 amperes, 83·5 volts, 2·2 electrical horse-power, 1·46 B.H.P. Running it as a generator, it made 1,100 revolutions, 19 amperes, 85·8 volts, 1·67 electrical horse-power. In conclusion, he congratulated the author and the profession at large on this very excellent Paper (applause).

Mr. E. W. SMITH referred to the short-circuiting in the dynamos caused by the brushes. There were two arguments for it and one against it. Prof. Ayrton had given the one against it. Prof. Silvanus Thompson, however, holds that you should short-circuit the coils just so long that you can get up the same current in the opposite direction ready to fall into the circuit, so that there should be no effect of self-induction when the coil is passed into the other side of the brush. Another point was that though in the motor short-circuiting the coil has an effect on the field, in the dynamo it has not much effect on the field, because the armature field is so weak compared with the magnets. Of course the factor which determined how long you should short-circuit was whether you prefer some sparking and little effect of self-induction, or a greater self-induction effect and no sparking.

Mr. GUMPEL said that Mr. Snell's Paper gave them valuable information in connection with one of the most important subjects electricity could bring before them. It might be a dream, but he thought that electric motors would be in the future the principal point to which electrical engineers would direct their attention. Every indication pointed to that. The advantage of electricity would force itself upon the public at large, and then electrical engineers would be called upon to assist in dispensing with many of the cumbrous instruments at present used in daily life. Generally he agreed with Mr. Snell; this agreement might not, however, mean much, because there was hardly a second man in England who had such a long experience in motors as Mr. Snell. Having said that he would become heterodox, and attack the whole system in which these questions are dealt with. He disapproved of Mr. Snell's very first sentence:—"In discussing the design of electric motors, it will be necessary to first of all consider the relation between the dynamo and the motor." He entirely disagreed with that. He believed that the electric motor would find no greater drawback than its genesis out of the generator. If there were no generators, but simply electricity and its application, they could most decidedly attach electro-motors in a different manner altogether. He was, of course, referring to the reversibility of the dynamo. Prof. Silvanus Thompson, in a Paper read before the Society of Arts, stated that Clerk Maxwell, on being asked what he considered to be the greatest discovery in the last 25 years, replied:—"The reversibility of the dynamo." He wrote to *Knowledge* stating that surely Maxwell could not have said such a thing. Lenz's law, which was enunciated in 1834, contained within itself the reversibility of the dynamo.

Mr. KILGOUR suggested that in the case of a small motor the interest taken at the rate of 10 per cent. or so, and spread over the 2,000 hours or 1,000 hours a year, came to be a pretty considerable fraction of the electric energy put in. In the case of an 8 horse-power motor, it would come probably to as much as 15 per cent. That would have a considerable influence in transferring the point of maximum efficiency, and would bring it nearer to the point of maximum output.

Dr. WALMSLEY said that all his points had been anticipated by one speaker or the other. He congratulated the Association upon having such a Paper brought before it, and he congratulated Mr. Snell upon the very admirable Paper he had given them. Prof. Ayrton referred to the inadvisability of calling the second equation $\frac{\text{B.H.P. } 746}{n\,c}$ the back E.M.F. of the motor. Mr. Snell had explained to him that he did not intend it to mean that, only in the Paper by some oversight it distinctly appeared as the internal E.M.F. of the motor. If that were so, of course then the efficiency of the motor would be 100 per cent. He did not, however, object at all to expressing the loss in volts. They would notice that in so doing there was to some extent a distinct departure from the ordinary way of expressing the loss. If they took the L_d or the L_m which represented waste—he would not say "waste energy" because they were in volts—but if they took waste energy expressed in watts, and divided it by the current in the armature, then they had the expression L_d or L_m. So far he cordially agreed with Mr. Snell in thus expressing that waste energy. Its usefulness was emphasised by the curves which were given at the end of the paper. He would write the equations in this way—E_m the internal E.M.F. of the motor really equal to the E_T minus C R, which it must be. Then on the other side B.H.P. 746, divided by C plus L_m. This, therefore, would be the equation for the motor

$$E_T - C\,R = E_m = \frac{\text{B.H.P. } 746}{C} + L_m.$$

Part of that L_m was due to mechanical loss in the motor. Therefore it was a distinctly new way of writing that, except so far as anticipated in a curve of *that* kind [pointing to diagram given on page 314 of *The Electrician*.] The dynamo equation would be

$$E_T + C\,R = E_d = \frac{\text{B.H.P. } 746}{C} - L_d.$$

In Mr. Snell's equations there was no hint given as to how they were to ascertain what the speed of the motor ought to be. He rather fancied that, unless they got it out of those curves in some way, they could not determine by these equations whether the speed of the motor was greater than it ought to be or whether it was less (applause).

Mr. ESSON: About the Immisch motor; I should like to ask Prof. Ayrton a question. Was it a drum armature or a ring armature?

Prof. AYRTON: A drum armature, I believe.

Mr. ESSON said another question he would like to ask was this. When Prof. Ayrton sent the currents through the machine as a dynamo was the lead the same amount in a forward direction as it was in a back direction when he used it as a motor? He would like to make a few remarks in addition to those he made on the last occasion. The first point was with reference to the drum armature. Of course, in a drum armature the saturation was much less in the core than it would be in a ring armature, and his experiments were made with a ring armature. In the Paper which detailed those experiments he put in a term for the self-induction, as the expression was meant to be a general one, which would include cases in which the armature was saturated only to a small degree. Of course the self-induction became very important when they had a low degree of saturation in the armature. Prof. Ayrton said in all cases the E.M.F. of the motor was very much higher than that of the dynamo; but he (Mr. Esson) would point out that when they took the difference of potentials at the terminals of the motor and deducted from that C R, they were not then measuring the back E.M.F. of the motor. In sending a current through the motor they had to overcome, first, the electrical resistance C R; secondly, the back E.M.F. of the motor itself; thirdly, the E.M.F. due to self-induction. Therefore they were measuring the E.M.F. of the motor, plus something which depended on self-induction. Coming to the dynamo, when they took the difference of potentials at the terminals of the dynamo, and added C R, they had not got the E.M.F. of the dynamo, but they had got the E.M.F. minus the term which depends on self-induction. He contended that Prof. Ayrton in his experiments had been really measuring the self-induction of the machine, and the difference in the volts which he had got was equal to twice the E.M.F. due to self-induction. That was only on the supposition that he used the same back-lead in the motor as he did forward lead in the dynamo. It seemed to him to be a very simple thing to measure the self-induction, and it really ought to be measured. Then Prof. Ayrton would know exactly how much to put down to this, and how much to credit to the actual strengthening or weakening of the field. Mr. Snell had told him before the discussion that night that he had measured the back E.M.F. in the machine running as a motor and the E.M.F. in it running as a dynamo, deducing therefrom the strength of the field. In the one case—in the dynamo—he found that the E.M.F. was 14, while in the motor it was 14·9. Was that a drum armature?

Mr. A. T. SNELL: It was a ring armature.

Mr. ESSON said it was not very highly saturated, because the effective magnetism in C.-G.-S. units comes out at 13,720 for the dynamo and 14,602 for the motor. With reference to the compound windings of the Manchester dynamo of which Prof. Ayrton had spoken, it might be that the series was about half the shunt. That was a very common proportion. It was a proportion which they had in the Phœnix dynamos; but of course the series turns depended upon a great many things. They depended upon the turns in the armature; in fact, in their dynamos the series-turns in the magnets had always a certain fixed relation to the windings on the armature, and it depended also upon the degree of saturation and upon the self-induction. He had measured the compensation required and he had also measured what was required to raise the E.M.F. of the machine. It was a very easy thing to do. They simply took the saturation curve in the machine by separately exciting it with no current flowing in the armature. You mark the position of 100 volts, and then you see how many ampere-turns were required to raise it to, say, 105. When you have done this you find how many ampere-turns are required in the field-magnets

Digitized by Google

to raise the E.M.F. from 100 to 105 volts with the full current flowing. He found in the Phœnix machines that the waste turns—they might say the compensating turns, the turns really required to counterbalance the weakening effect—were about equal to the amount of ampere-turns required to raise the E.M.F. He also, while he was experimenting upon that subject, consulted Mr. Kapp, Mr. Swinburne, Mr. Sellon, and some other of his friends, and in most cases they had found about the same effect. The most peculiar instance was furnished by the Victoria dynamo, for there he thought the turns required to compensate the windings in the armature were four times the amount required to raise the E.M.F. from 100 to 105 volts when the machine was running with no current in the armature (applause).

Prof. AYRTON said with reference to Mr. Esson's pertinent question, the lead was unaltered during the whole of the experiments as a matter of fact because it could not be altered. The Immisch motor did not require an alternation of lead to vary the current. The armature had been run both ways, so that any advantage that could be obtained by varying the lead would have to be obtained either for the motor or for the dynamo. The numbers that it would be most right to take would be the highest values of back E.M.F. in the motor when run one way and the highest values of forward E.M.F. in the dynamo when run the other way. The highest values of the forward E.M.F. when the armature was run as a dynamo one way were lower than the back E.M.E. of the machine when the armature was running the other way. There was no question, therefore, as to the lead being suitable for the machine as a motor and not suitable for the machine as a dynamo. That answered Mr. Esson's question number one. Mr. Esson said if V_1 and V_2 were the differences of terminals, then

$$V_1 + C\,R = V_2 - C\,R,$$

where C was the current and R the resistance machine. All he could say was that they found it was not. They found that $V_1 + C\,R$ was different from $V_2 - C\,R$. Mr. Esson said, and it was perfectly true, that there might be a turn added for the effect of self-induction, but did not he rather uphold that self-induction was of no consequence in these machines? On the last occasion Mr. Esson said, "I concluded from that that the effect of self-induction might be neglected." Could not they with the same approach to truth conclude that the effect of self-induction might be neglected?

Mr. ESSON: No.

Prof. AYRTON said of course he did not want to in any way beg the question by a little bit of special pleading; but he did not think Mr. Esson had proved his point. Probably Mr. Esson had the same opinion about their experiments. The proper way to write what Dr. Walmsley had written down was not to express that loss as an E.M.F. or a potential difference. He thought that was rather misleading; he did not imagine that Mr. Snell meant by E_m what was commonly called the back E.M.F. of the motor. Mr. Snell meant that it was a kind of fictitious back E.M.F., but he (Prof. Ayrton) thought it was a mistake to introduce that fictitious back E.M.F. The proper way, he believed, was as Prof. Perry and himself wrote it in the Paper some seven years ago; that was to say, that C V (the watts applied to the motor) was used up in certain definite ways—all of which might be written down without difficulty. He did not know that there was any actual loss of volts due to reactions in the motor. What happened was that a certain amount of the mechanical power developed was used in grinding the spindle of the motor against its bearings, and in generating Foucault currents instead of being usefully given to the tool or machine driven by the motor. Commercially, that led, no doubt, to a distinct waste of power, but it was, he thought, a mistake scientifically to say that the motor did not develop a certain amount of mechanical power because that power was subsequently employed uneconomically. The fact was they used a part of the power of the motor in foolish ways. They ground metal against metal; that was their fault. And they also ground metal against ether, or something of that kind; but that also was their fault, it was not the fault of the motor regarded as a converter of the electric energy supplied to it into mechanical energy.

Mr. A. T. SNELL, in reply, said his primary object in writing the Paper was to elicit discussion, and he did not think he had failed, for both his mathematics and his practical reasoning and results had certainly been handled quite as roughly as he wished them to be. The debate had given them some very important and fresh data, which would set them all thinking, and would, perhaps, enable those who were practical men to make better machines in the future. He had also a second object—that was to bring before the Association a new method of designing, and that is that the motor should be designed primarily with reference to the torque, and not with reference to the horse-power. He regretted that this point had been missed in the discussion, and that the debate had rather turned upon the reversibility of the dynamo. His mathematics all through were intended to be of a practical character rather than strictly correct according to the Cambridge view. He fully agreed with Prof. Ayrton that mathematically the equations in the Paper would not stand; but to practical men, with all deference to Prof. Ayrton, *this* equation for the E.M.F. was of more importance than the elaborate analysis which Prof. Ayrton had put on the board, for the simple reason that they could use the one but could not use the other. The constants are absolutely indeterminate for ordinary practical men; but they could make a motor, and could determine the three quantities in his equation, and they then had all they wanted. It was not of so much importance to them to know whether they lost most of their energy by means of Foucault current, hysteresis, or by friction in the journals, as to know what was the total quantity of energy which was lost. He had got that in this diagram (p. 314, *The Electrician*). That gave him exactly the loss he had in the wire, and the losses other than $C^2\,R$. He was under the impression that *this* term, $\frac{\text{B.H.P. } 746}{n\,c}$, did not appear in Prof. Ayrton's Paper; but he was pleased to hear that he had been forestalled in that. As to Prof. Ayrton's remarks upon the design of motors with reference to their working, there was a certain current which a motor would work at without undue heating. That must be primarily determined. With that current they could do a definite number of foot-pounds per revolution. If the motor was designed, say, to run at 100 volts, and it required only 80 volts, it was of no great importance beyond the fact that one does not get quite as much horse-power out of it. But if, to do the work for which it is intended, it has to run at a higher current, it is absolutely useless, because it will seriously heat. In the dynamo, as a rule, it is chiefly necessary to look to the number of volts. One did not care so much about the number of amperes the machine would give. Mr. Esson had brought forward very strong reasons in favour of the opposite side of the main question; but that gentleman must have overlooked certain parts of the Paper, particularly in the commencement, in which it was distinctly stated that with large dynamos used as motors the same results would not be obtained as when small motors were used as dynamos. Almost all the experiments mentioned in the Paper were made with machines which had been especially designed with reference to their work as motors and not as dynamos. He had, however, made a special experiment a few days ago with a machine that was specially designed as a dynamo. He had placed upon the board a well-known equation, $E = K\,W_a\,N_t\,A$, which gave the internal E.M.F. in terms of a constant, the number of turns of wire, the cross-section of the armature, and the value of the magnetism per square inch. The number of turns of wire was 576, the cross-section of the armature 59in., and the internal E.M.F.s were severally 381·2 and 302·8 volts. On making the calculation it would be found that the value of the induction in the dynamo was 14, but in the motor it was 14·9. Where did the extra magnetism come from? If the views of Prof. Ayrton and himself did not account for the extra magnetism, he was fairly at a loss to account for it. He had unfortunately no mathematical data to prove where this increase of magnetism is gained, but that it does exist he was sure, and the experiments that Prof. Ayrton had made with the assistance of the old students during the last few days with one of the Immisch motors fully confirmed the experiments he himself had made within the last 3 or 4 years (hear, hear). He would have raised the magnetic density if he could have done so, but at the time he had not got the steam power to do it. Prof. Ayrton had referred to the self-induction in the motor tending to increase the lead in the dynamo and to decrease the lead in the motor. It was necessary to explain that the lead in a motor was less than the lead in a dynamo, and the difference in machines of the Manchester type was oftentimes very marked. Frequently in the dynamo there would be a lead of 30 degrees, whereas in the motor there would not be a lead of more than 5 degrees. He was inclined to explain that in this way. It was a very rough explanation, but, unfortunately, it was impossible to get inside the armature, and we do not really know how the lines of force are distributed. *(Illustrating on the black board.)* Let this be a Manchester field, with a ring armature put in it, the brushes being practically on a horizontal line, so that there is no lead. In the motor the lines of force do not pass straight through the armature, but they pass somewhat as shown in the diagram, and the result is that the attraction is greater than the repulsion—the pole of the field, in fact, is very near to the pole of the armature. The resultant pole is always ahead of the brush. The result is that in a motor, although we have a slightly negative lead as regards the position of the brush, yet the resultant pole in the armature itself may be ahead of the horizontal line, and may, apparently, be actually positive. There may thus be a motor-armature strengthening the field, although the brushes themselves stand, perhaps, with a negative lead of 5 degrees. He did not think there was any mathematical proof of this; he had tried very hard in various ways, but he could not substantiate any theory on the subject. The difficulty arose from the fact that the position of the resultant pole varies with every change in the current. If the field, for instance, is increased very much the pole will probably be very far forward, and right underneath the corner of the field; but if the current is decreased the chances are that it will go back, and *vice versâ*. Prof. Ayrton was also kind enough to call attention to an oversight in the Paper in the expression put down for the torque. The equation was really in C.-G.-S. units, and was quite correct as it stood. He thought Prof. Ayrton would grant that. At any rate he thought it appeared in all the text-books, so that if the Paper

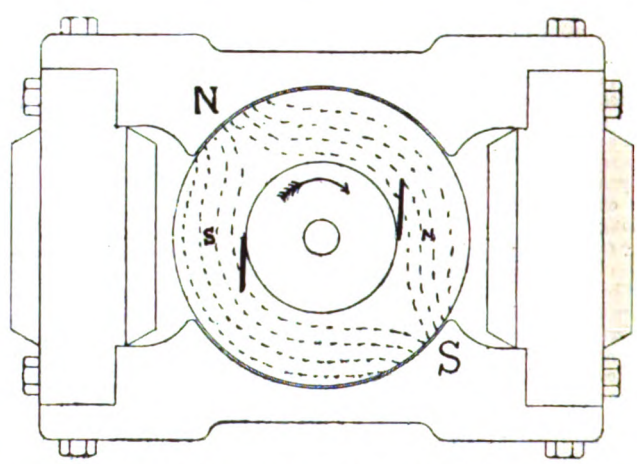

Diagram showing probable position of resultant field in a motor with zero lead

Digitized by Google

here was wrong the text-books also were wrong. All through the Paper he had been reasoning in foot-pounds, amperes, and Kapp lines. He ought, therefore, to have put the proper constant in ; but Dr. Walmsley had been kind enough to calculate it, and he would put it on the board.

$$T = \frac{Z_a C_a N_t}{2\pi} \times \cdot 00004432.$$

where T = lb ft.
Z_a = Kapp lines (total No.)
C^a = amperes.
N_t = total No. of turns.

It was rather formidable. The torque there was expressed in foot-pounds. He had forgotten what the constant was, but it was a large quantity. If there was any slip in those figures the students could easily verify it for themselves. Another point raised by Prof. Ayrton was why he (Mr. Snell) advised a field relatively stronger as the size of the machine increased. He did that principally as a result of experience. Experience seemed to point to the fact that as a machine got larger it was advantageous to increase the size of the field. He was, however, willing to concede that the principal reason was the question of cost. A large armature was very costly, and as a rule with big machines the question of weight did not enter into the problem very largely, so that it was cheaper to make a big machine with a small armature and a relatively powerful field, than it was to make one with a large armature and a weak field ; but he had no doubt that if it were wanted to make the experiment they could design a 100 horse-power machine practically on the same lines as one of 1 horse-power.

Prof AYRTON : You have no reason except the cost ?

Mr. SNELL replied practically none, with this exception, that the larger the machine the greater the leakage ; the result is that there is a greater difficulty in maintaining a given concentration of magnetism in the armature. Supposing they wanted to obtain 16,000 C.-G.-S. units in the armature, they could not with the same proportionate field do it ; they would have to increase it a trifle. The increase in a 50 horse-power machine might be probably 10 per cent. over what it would be in the case of a 1 or 2 horse-power machine. He could state this most distinctly, that in all cases where a dynamo and a motor have to be designed with a given armature, a very much smaller field can be used for the motor than for the dynamo. Probably if they could thoroughly analyse the very important equations put upon the board by Prof. Ayrton, they would find the value of the constants ; but the matter was practically an extremely difficult one, and that was why he had been led to use equations of a practical character rather than strictly mathematical ones. He would like to say a few words with reference to the use of the quantity $\frac{\text{B.H.P. } 746}{n\ c}$ before sitting down. It really was an E.M.F. ; that could be seen at once. The B.H.P. multipled by 746 gave the total quantity of watts. It was not known what E.M.F. was there at any time, but the current was known. If they divided by the current they must have a quantity left which is of the order of volts, and that he would prefer to call the *effective* E.M.F. of the motor. That in practice was what one wanted. The theoretical back E.M.F., namely (E – C R), was not of so much importance as the actual effective number of volts ; if they had the latter they had a measure of the efficiency of the machine. He thanked Mr. Reckenzaun for his remarks. He was pleased to hear that Mr. Reckenzaun had found that a dynamo in a given case required 60 per cent. more speed to make the same E.M.F. with the same current as it did when run as a motor. This thoroughly bore out the results of his own experience. With regard to efficiency, the curves (*The Electrician*, Jan. 8, p. 312) were taken from a by no means efficient machine. The maximum horse-power was got from a point where the efficiency was low. With a well-designed machine a large variation of the load did not have a very great effect on the efficiency. He could vary the output by probably 30 or 40 per cent. on either side without obtaining any very great difference of efficiency. They could notice how very steep the curve was on the rising limb. If the load were varied by a very small amount when working on this side of the curve we should get down to one-half the efficiency. He thought they would see that clearly on reference to the curves given in the Paper. He hoped before long to have an opportunity of putting before the Association what he might call curves from a normal Immisch motor (applause).

On the motion of the PRESIDENT a cordial vote of thanks was awarded to Mr. Snell for his Paper, and the proceedings then terminated.

"MODERN VIEWS OF ELECTRICITY."

The following paragraphs, which form the conclusion of the remarkable series of articles under the above title, by Dr. Oliver Lodge, are reprinted (by permission) from *Nature*, of January 31 :—

Conclusion.

"Conclusion" is an absurd word to write at the present time, when the whole subject is astir with life, and when every month seems to bring out some fresh aspect, to develop more clearly some already glimpsed truth. The only proper conclusion to a book dealing with electricity at the present time is to herald the advent of the very latest discoveries, and to prepare the minds of readers for more.

Referring back to Part IV., Vol. XXXVIII., p. 418, we spoke confidently of a radiation being excited by electric oscillations, a radiation which travelled at the same rate as light, which is reflected and refracted according to the same laws, and which, in fact, is identical with the radiation able to affect our retina, except in the one matter of wave length. Such a radiation has now been definitely obtained and examined by Dr. Hertz, of Karlsruhe, and in the last month of last year, Prof. von Helmholtz communicated to the Physical Society of Berlin an account of Dr. Hertz's latest researches. The step in advance which has enabled Dr. Hertz to do easily that which others have long wished to do, has been the invention of a suitable receiver. Light when it falls on a conductor excites first electric currents and then heat. The secondary minute effect was what we had thought of looking for, but Dr. Hertz has boldly taken the bull by the horns, looked for the direct electric effect, and found it manifesting itself in the beautifully simple form of microscopic sparks.

He takes a brass cylinder some inch or two in diameter, and a foot or so long, divided into two halves, with a small sparking interval between, and by connecting the halves to the terminals of a small coil, every spark of the coil causes the charge in the cylinder to surge to and fro about five hundred million times a second, and disturb the ether in a manner precisely equivalent to a diverging beam of plane-polarised light with waves about twice the length of the cylinder.

The radiation so emitted can be reflected by plane conducting surfaces, and it can be concentrated by metallic parabolic mirrors, the mirror ordinarily used being a large parabolic cylinder of sheet zinc, with the electric oscillator situate along its focal line. By this means the effect of the wave could be felt at a fair distance, the receiver consisting of a synchronised conductor with a microscopic spark gap, across which the secondary induced sparks were watched for. By using a second mirror like the first to catch the parallel rays and reconverge them to a focus, the effect could be appreciated at a distance of 20 yards. If the receiving mirror were rotated through a right angle, it lost its converging power on this particular light.

Apertures in a series of interposed screens proved that the radiations travelled in straight lines (roughly speaking, of course).

A gridiron of metallic wires is transparent to the waves when arranged with the length perpendicular to the electric oscillations, but it reflects them when rotated through a right angle, so that the oscillations take place along the conducting wires ; thus representing a kind of analyser proving the existence of polarised light. The receiver itself acted as analyser, however, for if rotated much it failed to feel the disturbance.

Conducting sheets, even thin ones, were very opaque to the electrical radiation ; but non-conducting obstacles, even such as dry wood, interrupt it very little, and Dr. Hertz remarks, "not without wonder," that the door separating the room containing the source of radiation from that containing the detecting receiver might be shut without intercepting the communication. The secondary sparks were still observed.

But the most crucial test yet applied is that of refraction. A great prism of pitch was made, its faces more than a yard square, and its refracting angle about 30deg. This being interposed in the path of the electric rays, they were lost to the receiver until it was shifted considerably. Adjusting it till its sparks were again at a maximum, it was found that the rays had been bent by the pitch prism, when set symmetrically, some 22deg. out of their original course, and hence that the pitch had an index of refraction for these 2ft. waves about 1·7.

These are great experiments. As I write, they are but a month old, and they are manifestly only a beginning. They are very simple ; I have repeated some of them already. They seem likely to settle many doubtful points. There has been a long standing controversy in optics, nearly as old as the century, as to whether the direction of the vibrations was in, or was perpendicular to, the plane of polarisation ; in other words, whether it was the elasticity or the density of the ether which varied in dense media ; or in Maxwell's theory, whether it was the electro-magnetic or the electrostatic disturbance that coincided with that plane. This point has, indeed, by the exertion of extraordinary power, been almost settled already, through the consideration of common optical experiments ; but now that we are able electrically to produce radiation with a full knowledge of what we are doing, of its directions of vibration and all about it, the complete solution of this and of many another recondite optical problem may be expected during the next decade to drop simply and easily into our hands.

We have now a real undulatory theory of light, no longer based on analogy with sound, and its inception and early development are among the most tremendous of the many achievements of the latter half of the nineteenth century.

In 1865 Maxwell started his theory of light. Before the close of 1888 it is utterly and completely verified. Its full development is only a question of time, and labour, and skill. The whole domain of optics is now annexed to electricity, which has thus become an imperial science.

A "UNIVERSAL" GALVANOMETER.*

BY DR. A. D'ARSONVAL.

The instrument which I am about to describe was devised specially to meet the requirements of physiological research. It is a tangent galvanometer of the Wiedemann pattern, and embodies the numerous modifications of which practical experience has taught me the value. It is dead-beat or ballistic as required, and it can be changed into a Nobili astatic, a plain Thomson, or a differential Thomson galvanometer by a simple alteration of the magnetic equipment. It has therefore the great merit of meeting all requirements in a single instrument of great precision and comparatively low price. One important point consists in the complete separation of the coils and the part of the instrument carrying the needle and damping apparatus, which greatly facilitates alterations and transport. I will now describe the two portions separately.

FIXED PART.—Fig. 1 represents the galvanometer in perspective, Fig. 2 being a section through the moving parts of the instrument. On the circular plate P there is a graduated rod, R, carrying the coil frames. This plate is supported on three screws, only two of which, V V′, are adjustable. The line joining V V′ is perpendicular to R, so that it is only necessary to place these two screws in the magnetic meridian in order to have the instrument properly adjusted once for all. Two split pieces, E E′, slide on the rod R

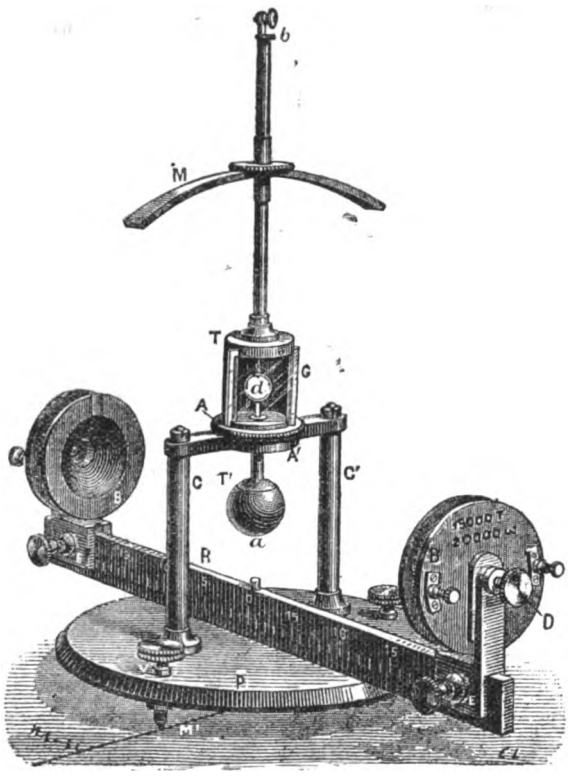

FIG. 1.

and they are provided with screws to fix them in whatever position required. The upper part of E E′ is furnished with a screw, D, which keeps the coils tight. The bobbins are hollowed out in order to receive the ball of the damping apparatus *a*. Each bobbin is provided with two terminal screws, and on it is written the number of turns of wire and its resistance in ohms. The changing of these bobbins is an easy matter. Each apparatus carries two sets—one of 150 turns and ·4 ohm resistance, the other of 15,000 turns and 20,000 ohms resistance for ballastic purposes and E.M.F. measurements. On either side of R rises a circular support, C and C′, joined at the top by a cross-piece, A′. This part of the apparatus is of copper, and always remains the same.

MOVING PARTS.—The moving parts (magnet and damping arrangement) also form a complete whole. The cylindrical box T is surmounted by a metal tube, carrying the compensating magnet M, and provided with a screw head, *b*, on which there is a small windlass upon which the cocoon fibre is wound. The lower part A is provided with a rim and just fits into the ring A′. This lower part ends in a small tube, T′, which terminates in a screw head, upon which the copper damper, A, is screwed. The drum T has an opening, G, fitted with glass, which is slightly oblique, to avoid the reflections which are so troublesome when the glass and mirror are parallel. The cocoon fibre, which starts from the windlass, terminates in a small hook, *c*, from which the mirror is suspended. The simple magnetic arrangement consists of a powerful little horseshoe magnet, weighing 1·5 to 2 grammes, and able to support 62 times its own weight. The magnet is screwed to a wire, which fits by friction in a socket in the frame of the mirror *d*. The mirror can therefore be set in any azimuth. The damper consists of a copper ball, *a*, which screws on to T′; it is pierced by a cylindrical hole, in which the magnet turns, with 1 millimetre play all round. As the sphere is 4 centimetres in diameter, while the external diameter of the magnet is only 1 centimetre, the damping effect is considerable, even without making the instrument astatic, and, moreover, it remains the same in every azimuth. It is easy to see that there is no difficulty in moving the damper without touching the needle, and replacing it by a simple thin brass ball, by a less powerful cylindrical damper, *e*, or by a variable damper, *f*. The variable damper consists of a ring of copper which slides inside a split cylinder by means of two studs, and a ring which fits on to the external threads of the cylinder, as shown in *f*. According as the magnet is more or less surrounded by the damper, the damping effect is altered. One can also use a liquid damper consisting of a thin brass ball filled preferably with ordinary petroleum. If the directing magnet M is taken off, we simply have a tangent instrument. To make it an astatic instrument of the Haüy type, it is only necessary to replace M at the proper height in the ordinary manner. If it is desired to use the galvanometer as an astatic

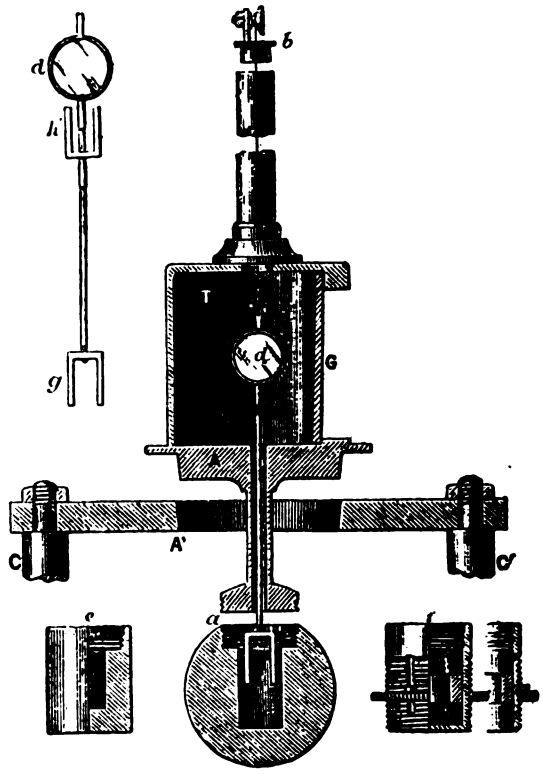

FIG. 2.

galvanometer of the Nobili pattern, we merely screw on a second magnet, *h*, similar to *g*, taking care to oppose the poles. Finally, the whole magnetic apparatus can be taken out and replaced by a single or double Thomson equipment, employing if desired the liquid damper, which is very efficacious in this case. It is extremely easy to change the cocoon fibre by merely unhooking the mirror and taking off the top of the tube. The windlass is very small, so that the directing magnet M can be taken off or put on without altering the suspension. When the instrument is turned into a Haüy astatic galvanometer, the damping effect is so powerful that it is necessary to diminish it by replacing the ball *a*, either by the cylindrical damper *e*, or by the variable damper *f*. The readings are taken either off a transparent scale or off the micrometer scale, which I have previously described. In the latter case the sensitiveness becomes 25 times greater for the same angle of deflection. This method of reading is very valuable when the instrument is used as a tangent galvanometer. In another article I shall describe the necessary alterations for the measurement of E.M.F., resistance, capacity and temperature, &c., as well as the optical method which permits of a large audience witnessing these readings. It is on account of the multiplicity of uses to which this instrument can be put, that I have called it a universal dead-beat galvanometer. The successive modifications, which daily experience taught me to be necessary, were carried out in the workshops of M. de Branville, 25, Rue de la Montaigne, Sainte Geneviève.

ON THE ELECTRIFICATION OF METALLIC PLATES BY ILLUMINATION WITH THE ELECTRIC LIGHT.*

BY W. HALLWACHS.

The author refers to a previous Paper, in which he showed that illuminated plates receive thereby an electrostatic charge (Wied. *Ann.*, XXXIII., p. 301). These charges are of the same order as those produced by the contact potential difference between two metals.

To test this charge he takes a circular metallic plate, 8 centimetres in diameter, and suspends it by an insulated wire inside a cylindrical vessel, whose axis lies horizontally. This cylinder is made of sheet iron, and is 50 centimetres long and 37 centimetres diameter. The cylinder was rusty and stood on a stand leading to earth. The part electrically connected to the stand was well cleaned. The wire suspending the plate led to a Hankel electrometer, and to prevent its receiving extraneous charges it was protected by brass tubes connected to earth and surrounding it.

The electrometer was of small capacity. In one of the (vertical) ends of the cylinder was a centrally placed hole covered by a brass wire gauze, and through this the light came which fell on the plate. The hole was of the same size as the plate. The light was 45 centimetres from the gauze, and was on the axis of the cylinder and suspended plate. The gauze protected the suspended plate from the direct action of the current in the arc lamp. This effect could be detected if the gauze was removed.

The cylindrical screen was of rusty sheet iron in order that its contact potential should be always negative to that of the suspended metal plate. By this means the effect of illumination could always be distinguished. For if the plate had been negative to the cylinder, the illumination might possibly increase the potential of the plate by driving away its negative charge; but if the plate is positively electrified, and is then illuminated, we should only expect a rise in potential if + electricity were generated by illumination. The contact E.M.F. between rusty iron and clean zinc is $-1{\cdot}2$ volt.

If the rays of the electric lamp were screened by mica the illumination had no effect on the plate; but when they passed through a plate of isinglass much thicker than the previous mica one the electrometer showed a gradually increasing positive charge; the mica plate on being inserted checked the increase of the charge. The rise of potential cannot, therefore, be due to inductive action nor to temperature effects. It must be purely an effect due to illumination.

The metals tried were zinc, brass and aluminium. The illumination always charged them positively, but only if they had clean surfaces. Dirty plates showed no effect.

The effect of any illumination is to decrease the magnitude of the maximum positive charge which any subsequent illumination can produce. The plate becomes fatigued, as it were, by constant illumination. The magnitude of the *maximum* rise in potential was for zinc over a volt, for brass about a volt, and for aluminium $0{\cdot}5$ volt.

LEGAL INTELLIGENCE.

In re Gaulard and Gibbs' Patent.

COURT OF APPEAL.—TUESDAY, JANUARY 22.

Mr. MOULTON then addressed the Court on behalf of the respondents. He said Mr. Aston attempted to escape from his enemies very much as the cuttle-fish did—not by proving his case was right, but by making it almost impossible to see through the argument, which was inconsistent and obscure. There had never been any adherence to any one interpretation, and the very thing which had enabled Mr. Aston to do that without instant detection was the fact that the patent did not define the invention in a way which would give one a clear idea of it. That very fault was most fatal to a patent. (The learned counsel then exhibited the machine, which was in the court below when Sir William Thomson gave evidence.) The high tension could not form in any way the basis of a patent, and it was not novel. That there must be a proportionate pressure to send the required current through the wire was perfecly well known, but here was not one single atom of information about it in the specification. It was claimed that a stepdown was part of the patent. It was suggested that the mention of light and motive-power made it a specified essential of the patent that the secondary should be in low tension. If it was essential to the patent, it was not so stated in it, and the patent must be bad. He asked the witnesses, until he was tired of doing it, "Can you point to a single word in this specification, provisional or complete, which indicates any special tension in the secondary?" and every one of them said he could not. According to Gaulard and Gibbs they might have taken out a patent in the very same words as Jablochkoff, and said it was novel. Why? Because in Jablochkoff's time the fashionable lamp was a high-tension one, now it was low tension. No electrician spoke with the same authority all over the world as Sir William Thomson, and he gave his evidence with the most remarkable impartiality. He said there was nothing in the specification to indicate that it was necessary to use low tension. Mr. Aston said that a special generator was essential to the combination; and there was no attempt made by any witness on the other side to show that it would be novel if there was not a special form of generator. The things that were done were just as much Jablochkoff, and Edwards and Normandy, and Marcel Deprez perhaps more than anybody, as they were Gaulard and Gibbs. Jablochkoff's system was most clearly set out in a manner which would have conveyed far more information than Gaulard and Gibbs did, because it was conveyed without any tinge of error, and in a way which would excite the respect and attention of electricians, instead of being mixed up with matter which would lead them to reject it. Jablochkoff's was practically known in England, and yet it had never been tested, and it was one or two years before Gaulard and Gibbs came into practice. That there was this interval before being used did not make Gaulard and Gibbs invalid, nor did Jablochkoff's not being used make it any the less part of the knowledge of the world.

To support the patent, two things were necessary—the claim must make it clear that the generator was of special form, and it must be shown that they had told the world what was that special form. The patentee had defined two induction coils perfectly, down to the last screw, but he did not define any class. He hoped their lordships would protect them from this—that a man, by describing the numerical dimensions of an instrument which embodied his invention, without stating what were the essentials of that invention, would be able to put any interpretation on those numerical descriptions, so as to make them include any invention that he liked, according to the events which happened after his patent. He defied anybody reading the specification to find out the special class of the generator.

If the public were supposed to look at the anticipations with the same instructed eyes with which they were supposed to look at the specification, it would be seen that over and over again this was anticipated. But above all he took Jablochkoff; first of all because Jablochkoff was entitled to the merit of this idea of distribution. It was Jablochkoff who pointed out that you could give a man a different kind of current from that supplied to his neighbour. It was admitted that Jablochkoff might have worked with high tension, although he did not mention which tension; he left that to the electrical engineer. It was published by Jablochkoff in a way in which it could be used with any tension, with any number, and to any distance. Then how could it be said that after Jablochkoff there was anything to publish? Jablochkoff did not limit the tension in any way; he took a current that gave him his result. The advantage of driving to a long distance with high-tension currents, on the evidence of the patentees themselves, was common knowledge. Dr. Fleeming Jenkin, in his report, said the appellants' system was founded "on the well-known principle that it is economical to use high-tension currents in driving to a distance." In trying to show the novelty of Gaulard and Gibbs' system, Mr. Aston had referred to Sir William Thomson's speech, where he pointed out that if you want to distribute electricity from Niagara it must be turned to a high-tension current, and distributed at a high tension for the very purpose of sending it to a distance in the form of a high-tension current. Economically there is no difference between a high tension with alternating currents and a high tension with direct currents. When people obtained provisional specifications before going to the expense of complete specifications, they made careful inquiries as to previous patents. He consequently had not the slightest doubt that Jablochkoff's patent had stifled a great number of provisional specifications. If Edwards and Normandy had said, "In the face of Jablochkoff can we get a patent for general distribution by secondary generators?" a prudent adviser would have said, "Certainly you cannot; you can only claim for some detailed improvement in the means."

Mr. ASTON then replied on behalf of the appellants, his final argument occupying nearly two days.

At the conclusion of the learned counsel's argument their lordships reserved judgment. Their lordships also intimated that the arguments might have been shortened, Lord Justice Lindley observing that four days would have been ample instead of the ten days occupied in the hearing.

Watt v. Maxim-Weston Electric Light Company.

In the Chancery Division of the High Court of Justice on Friday last, before Mr. Justice North,

Mr. HIGGINS, Q.C., moved on behalf of the plaintiff, Mr. Hugh Watt, for an interim injunction to restrain the defendants until the trial of the action or further order from carrying into effect a scheme of reconstruction of the defendant company as resolved upon by certain resolutions dated December 21, 1888, and January 7, 1889, and also from entering into and carrying into effect the agreement referred to in the scheme; or, in the alternative, for an injunction to restrain the defendants, the letters patent, and assets of the company in pursuance of the scheme until reasonable security for the amounts payable to the plaintiff should have been provided.

Mr. COZENS HARDY, Q.C., said the defendants were prepared to maintain that the proposed reconstruction was regular, and that the security given to dissentient shareholders was ample; but at the same time, the defendants were willing to deposit in the joint names of the solicitors a sum which would satisfy the plaintiff.

Mr. JUSTICE NORTH directed the motion to stand till the trial of the action, the costs of the motion to be costs in the action.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *January 26th*, 1889.

An extremely important decision has been rendered by the United States Supreme Court in the patent case of the Bate Refrigerating Company against Geo. H. Hammond and Co., which has a direct bearing on electric light interests in this country. As you are aware, it has been held by a number of litigants for some time, and they have been sustained in their views by some of the United States Circuit Courts, that an American patent was limited by the duration of any similar foreign patent which had been previously secured; and this principle has had the practical effect of bringing under suspicion of invalidity a large number of early electrical patents, especially those of Mr. Edison. The Edison Company has therefore had particular interest in the issue of the present suit, and has taken an active part in fighting it through. One of the grounds upon which the Bate Refrigerating Company had lost its suit against the Hammond Company in the Lower Court was that the patentee had taken out in Canada a patent for the same invention prior to the issue of the United States patent, the shorter term of which Canada patent had expired, so that, therefore, the United States patent was also at an end. The Court says: "The holding of this Court is that, inasmuch as this Canada Act providing for this extension was in force when the United States patent was applied for, and when the United States patent was issued, and under the provisions of the Canada Statute, the extension was a matter of right, at the option of the patentee, on his payment of a specified fee, and inasmuch as the fifteen years' term of the Canada patent was, on the facts of the case, continuous and without interruption, the United States patent does not, under the terms of Section 4,887 Revised Statutes, expire before the end of the fifteen years' duration of the Canada patent. We further hold that it was not necessary to the validity of this United States patent that it should have been limited in duration on its face to the duration of the Canada patent, but it is to be so limited by the Courts on evidence in pais, so as to expire at the same time with the Canada patent, that is with the same time as the extension, not running, however, more than 17 years. This is sufficient to dispose of the case. Another question was earnestly discussed in the case by both parties, but as we do not find it necessary to the decision of the case we do not find it necessary to determine the question, nor do we regard it as proper to do so. That question was this: It was contended by the appellant, as a further ground for reversing the decree, that the words of Section 4,887, 'first patented, or caused to be patented, in a foreign country,' do not mean before issuing or date of the grant of the United States patent, but means patented or caused to be patented before the date of the application for the United States patent. We do not consider or pass upon that question." As far as I understand this decision, it affects at least twelve of the Edison patents, including such fundamental ones as those on the broad invention of the filament lamp; the use of the high resistance enclosed conductor in a vacuum chamber entirely of glass; the use of a lamp removable from the socket, and the making of the enclosed chamber of the lamp in two parts fused together; the perfection of the carbon filament by getting rid of the occluded gases by the heat of the current; the making the filament of bamboo or other fibrous material, having the fibres parallel through the length of the filament, and the broad feeder patent. This decision is also reported to have a revivifying influence on other electrical patents, such as that of Mr. Brush on compound winding. We shall probably know a little more about this, and when the full text of the decision is given out the parties to the various litigations will see how they stand. At present the decision is the main theme of conversation in electrical circles, and in the Edison camp has been hailed with the greatest delight. Naturally those who have been fighting against the Edison claims point to the fact that the patents have still to be confirmed strictly on their merits, and that this decision simply affects the question of the effect of a foreign patent upon a United States patent under certain conditions. There is a feeling of satisfaction, however, at seeing the Supreme Court once more pronounce in support of patents, especially in a case where the inventor was so liable to suffer from no fault of his own, and really because he was anxious to proclaim to the world at large the fact of another triumph of American genius and skill.

Another important event in the electrical field this week has been the consummation of an arrangement or agreement between the Westinghouse Electric Company and the United States Electric Light Company. This does not appear to be so much a consolidation as a combination of interests, or, to use a much-abused word, a form of "trust." It is provided that the interests of the two companies shall be conducted hereafter for their mutual benefit, not only in the production of apparatus, but in the offensive and defensive use of their patents. It is said that the new combination has control of several hundred patents, and will represent a united capital of about ten millions of dollars. The United States Electric Lighting Company is, as you are aware, one of the oldest electrical concerns in the country, as the Westinghouse is one of the youngest. It has done a large amount of work, though perhaps not as much as might have been expected from its early organisation, and from its enjoyment of the assistance of such well-known men as Maxim, Moses G. Farmer, and Edward Weston. The Westinghouse Company is evidently bent on adding to the number of its alliances and strengthening itself in every possible way. In addition to the new arrangement with the United States Company, it has control of the Waterhouse arc lighting system and of the Tesla alternating-current motor, as well of the Sawyer-Man incandescent lamp. It will be seen that this makes a strong combination. It remains to be seen whether the companies concerned can hold together for any length of time.

I have advised you from time to time of the various agitations started in different parts of the country for the reduction of telephone rates. So far none of these agitations have been attended with any marked results, beneficial or otherwise, except in Indiana, where the legislators certainly did succeed in cutting off their nose to spite their face, and managed to deprive many of their constituents of the use of the instrument that has now become so necessary in local communication. The ill success of these serious movements might well have discouraged any attempts at new ones, at least until the patents run out; but I suppose that, like the poor, the telephone agitator will be always with us. He has resumed the work in Missouri, where there is a Bill before the Legislature, and the movement has also been resumed in Ohio, where it is proposed to cut down telephone rates to $3 a month. In this State a bill has just been presented to the Legislature at Albany, providing that the subscription in cities of 500,000 inhabitants and over shall not exceed $6 per month, and in all other places $3 per month. It may have struck you as peculiar that a division should have been made with regard to cities "of 500,000 inhabitants and over." The object of this neat little clause is to get round the provision in our State Constitution, that there shall be no special legislation of this nature affecting particular localities. Of course, as will be seen, this is not special legislation of an obnoxious character against which the Constitutional provision is made; but as New York and Brooklyn are the only two cities in the State that are over 500,000 inhabitants, there is no need to name them; and the little bill, should it become law, would have just the same effect as though they had been specifically mentioned.

Some interesting work is being done at the present time by the Pullman Palace Car Company in connection with lighting up trains by electricity. This company has been at work in that direction for some years past, and more recently has formed an electric department of its own at its big works near Chicago. The line of work upon which the company is experimenting at the present time is a little bit different, perhaps, from that which we have heretofore seen. If I am not mistaken the two methods hitherto followed in this country were those of charging a number of cells at the termini of the road, and then exchanging them, or else connecting up the generator with the axles of the baggage car

Digitized by Google

and thus charging the cells on the train whenever the train is running. The first method is the only one that has had practical utilisation worthy of mention. The Pullman Palace Car Company, however, in making up their special trains, such as that, for instance, which has just been put on to run three times a week between this city and Jacksonville, Fla., has placed on one of the cars a complete plant, which takes its steam from the locomotive. This plant comprises a small 3-cylinder Brotherhood engine, an Eickemeyer "iron-clad" dynamo, and 32 cells of electrical Accumulator (E.P.S.) Company's battery. The exhaust steam from the Brotherhood engine is used for heating the cars. This plant is economical of space, not occuping a greater floor area than 6ft. by 3ft.; but I have been given to understand that the engine, in spite of many merits, is not altogether satisfactory, the noise made being a very objectionable feature, especially in "vestibule" trains, which are practically a single unit. The racket of the engine whenever the train stops is quite disagreeable. Hence, there is still room for improvement, but it is said that the dynamo answers its purpose admirably.

NOTES FROM GERMANY.

(FROM OUR CORRESPONDENT.)

The past year has witnessed a great advance in the application of electricity, especially as regards electric lighting from central stations. Of course, the capital of the German Empire is far ahead in this respect. The use of electric light in the busy centre of Berlin has increased in an undreamt of manner. Five years ago the Allgemeine Electricitätsgesellschaft started the first small plant in Friedrich-strasse with a capacity of 2,000 16 candle-power lamps. Later on, when the company was allowed to lay cables along and below the streets, the second station was built in Markgrafen-strasse, where, to save space, the boilers had to be placed above the engines. The station in Markgrafen-strasse had six engines of 170 horse-power each and 18 dynamos, driven through belting. The station in Mauer-strasse, which was erected soon after that in Markgrafen-strasse, is very similar, and had originally three engines of 170 horse-power. This latter station was enlarged in 1887 by three further engines of 170 horse-power each, so that in the fall of that year these two stations possessed together 2,400 horse-power. This motive power being fully used in the beginning of 1888, the several stations were much enlarged. The station in Markgrafen-strasse received an addition of 1,200 horse-power, and was joined to the station in Mauer-strasse, whence the arc lamps that light the "Unter-den-Linden" are supplied with current. These two stations have now 3,900 horse-power available. In a short time two further stations in the Spandauer and the Dorotheen-strasse will be erected, each of which is intended to feed 20,000 incandescent lamps. Preparations have also been made to further enlarge the existing stations, so that the Berliner Electricitätswerke will dispose shortly of no less than 14,000 horse-power. Great economies have also been effected in working. The cables of the three stations in Markgrafen, Mauer, and Friedrich-strasse have been united, and thus it has been rendered possible to throw the expensive daily service during winter, and the total supply during summer, upon one station only. It may be interesting to state that in these plants vertical 1,000 horse-power engines, with double cylinders, are in use. The gas journals assure us that the extent to which electricity is used at present in Berlin is unequalled in Europe. Whether this be true or not, it is certain that in some districts of the German capital the demand for light has more than doubled, and that in addition there is a growing demand for electrical transmission of power.

Passing from the metropolis to the old city of Nuremberg, I may say that the Messrs. Schuckert have erected and started the plants for the Hamburg, Bremen, Luebeck, and Barmen stations. The free port of Hamburg has been provided with a station having a 5,000 16 candle-power lamp capacity, in addition to 33 12-ampere arc lamps. The plant comprises six dynamos for the incandescent lamps with a capacity of 360,000 watts, and six dynamos for the arcs with a total output of 36,000 watts. These dynamos are driven by belts from a common shafting. Four engines are used, three of which are 138 horse-power engines, whilst the fourth gives 50 horse-power. The larger engines are horizontal compound condensing engines, furnished by the Saechsische Maschinenfabrik at Chemnitz. The cylinders are 16 and 24 inches diameter respectively, the stroke is 32 inches, and the number of revolutions is 100 per minute. The normal output amounts to 138 horse-power, but it may be increased by change of the cut-off to 222 horse-power. The smaller engine is a horizontal high-pressure expansion engine, with a cylinder of 14½in. in diameter, and a stroke of 28½in., running at 90 revolutions a minute. The engines drive the shafting by means of ropes off the fly wheels, the dynamos being driven by belts. These dynamos are of the well known Schuckert type. The ampere meter for the total amount of current, as well as the rest of the ampere and voltmeters, are Hummel's galvanometers. The large ampere meter consists of a copper bar weighing 10 kilos, whilst the total weight of the movable parts only amounts to 7 grammes. The instrument measures up to 2,500 amperes. The incandescent lamps are divided into 15 circuits, each of which is provided with an automatic tension regulator. The mains are provided with double lead covering, and are laid underground in U-shaped iron boxes. The 33 arc lamps are divided into three circuits. The Bremen plant has a capacity of 2,000 16 candle-power incandescents and 80 12-ampere arcs, an increase of 150 per cent. being anticipated. The arcs and incandescents are run off the same dynamos, for which reason the former are connected two and two in parallel with the glow lamps. The plant comprises four 67,000 watt dynamos, and two 180 horse-power engines. The dynamos are driven directly through belting. The engines are vertical compound condensing machines, the cylinders having a diameter of 15½ and 26¾ inches respectively, with 20-inch stroke. The output at 150 revolutions per minute amounts to 180 effective horse-power, which may be increased by changing the cut-off. Each of the engines has two belt fly wheels of 8½ feet in diameter. The system of distribution is the same as at Hamburg. Most of the arc lamps are fed by special feeders, so that of twelve circuits ten belong to incandescent and two to arc lights. The length of the mains varies between 100 and 1,900 metres; the loss of potential in them at the highest possible output is 15 volts. Every main has two tension wires, and consists of a double lead-covered cable, put either in one of the iron boxes mentioned above or into channels in the quay walls. Other German towns have also built central stations, Elberfeld being the first and Barmen the second town which opened a central station at its own expense. The station at Barmen was started after a great deal of hard and troublesome work. For the present it has to supply 2,000 16-candle-power lamps by means of four dynamos, but it is designed so that it can be easily made to supply 6,000 lamps. The third town was Darmstadt, where the three-wire system has been brought into use; but as long as the service was provisional the lamps were run from the two external wires only. The station supplies the theatre with 2,400 lamps, and a total of about 5,000 lamps. It was built by Siemens and Halske, and the dynamos used are shunt-wound, with internal poles directly coupled on the shaft of Kühn's engines. These small, elegantly-built and beautifully working engines, which run at from 200 to 220 revolutions per minute, are at present very largely used in Germany. Liegnitz, Görlitz, Leipzig, are preparing for central stations. Frankfort-on-Main, whose grand central railway station has been lighted by arcs (incandescent lamps being used only in the waiting rooms), wants to spend about three millions of marks on a central lighting station. Marienthal, the famous Austrian bathing-place near the German frontier, will next season be illuminated by arcs and incandescent lamps. Ganz and Co., of Budapest, will build this station, and supply the town with current by means of their alternating current transformers. Alternating currents are, generally speaking, very little in use in Germany up to the present.

The first number of the *Elektrotechnische Zeitschrift* contains a Paper read before the Elektrotechnischer Verein by A. du Bois Raymond, dealing with the difficulties that occur in the transmission of power by alternating currents. The Paper is very ably written, and every possible effort made to prove that continuous current motors are much to be preferred. The author states that a common continuous current motor, whose magnet cores are built up of insulated sheet-iron, will never yield the same output with alternating currents, as the iron grows very hot, the sparking at the brushes increases with increasing output, and, in addition, the output depends upon the difference of potential at the terminals. If we try to improve the result by short-circuiting the armature and sending the alternating current only around the field-magnets, we can reach the same output and efficiency as with a continuous current. But we shall have the same relation between output and potential difference at the terminals as before. Passing to the synchronous type of motors, we find the drawback that the load must always be kept below a certain limit, and that the efficiency increases with decreasing load. The Helios Company has lately patented a device which consists chiefly in coupling an ordinary continuous current motor together with a properly arranged commutator in such a manner that the alternating-current lead into the system is corrected by the revolution of the motor as long as synchronism exists. But this commutation, of course, is accompanied by further losses of energy, and, for an alternating-current of only 70 alternations per second, the motor would have to make 4,200 revolutions per minute in order to produce synchronism. Even in the Tesla motor the author finds many disadvantages. The magnetic circuit, he says, cannot be arranged so advantageously as in a continuous current motor, two windings having to be placed between armature and field magnets; and the work used to reverse the magnetism necessarily far surpasses that

Digitized by Google

used in a continuous current motor with the same output. This interesting and well-written Paper concludes with the pessimistic question, "Will time be able to overcome all these difficulties?"

SCANDINAVIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Swedish manufactory for incandescent electric lamps in Stockholm, belonging to the firm of R. W. Strekleuert and Co., will be again extended, the works having already been taken in hand. The annual production will thereby be raised to a maximum of 1,000,000 lamps, and the manufactory thereby becomes the second of its kind, number one being the Edison Company's in America, with a production of about 1,800,000 lamps per year.

In Sweden electric light has recently been introduced in several railway carriages, and it is now also contemplated to adopt this mode of lighting in the mail cars on the Helsingborg-Hessleholm and the West Coast Railway, and will probably soon be generally adopted.

In Stockholm a central station for electric light was opened on Dec. 1st by the Stockholms Elektriske Belgsningsakliebolag. The installation comprises three dynamos from Siemens and Halske, but another will soon be added to this number. Each dynamo has a capacity of 1,000 16-candle incandescent lamps. The Crown Prince of Sweden is at present the largest subscriber.

Several Swedish towns have already adopted, or are about introducing, electric light for the lighting of the streets. At Eskilstima the Corporation has just decided to have the streets of the town lighted by electricity. Luiea, too, is likely soon to be lighted by electricity, and will probably be the most northerly town in the world where this mode of lighting is used.

Even in Copenhagen, where the electric light is very slow in making friends, shops are now beginning to adopt it, and the Corporation has recently sent out an engineer to various countries, so as to get some idea of what folks are doing in other capitals and big towns. A good-sized installation has just been carried out, viz., that of the National Theatre, Restaurant, &c. The engine and boiler rooms are entirely underground; there are two 30 horse-power boilers of De Nayer's safety tubular system, and two engines of 26 horse-power each. There are two of Schuckert's dynamos, and the installation comprises some 28 arc lamps, and 250 incandescent lamps.

Although the installation has cost about £3,300, a considerable saving is reckoned upon, and it is expected that the electric light will cost some £500 less per annum than did the gas. Besides, there is a surplus of electric power, which can be let to the neighbouring shops, &c., so that the "National" installation, in fact, becomes the first, albeit modest, central electric station in Copenhagen.

The number of conversations at the Stockholm General Telephone Company for each year since 1884 is shown in the following table:

1888.	1887.	1886.	1885.	1884.
8 007,282 ...	6,462,548 ...	5,802,063 ...	4,772,760 ...	2,332,082

The number of telephones owned by this Company on November 30th, 1888, was 4,493, against 4,015 the previous year.

Electrical tramways are to be introduced in the town of Sundsvall, in Sweden, the electrical engineers being the well-known firm of Messrs. Thomson-Houston, of Boston. The machine power is to be supplied by a waterfall near the town, so that of course the cost of working will be very small. Should the experiment be successful, other Swedish towns will follow this example, water power being almost everywhere plentiful. This will be the first electrical tramway in Scandinavia.

CORRESPONDENCE.

INDUCTIVE INFLUENCE BETWEEN DISTANT CIRCUITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I think it very probable that Mr. F. Higgins (*Electrician*, February 1st, page 378) may be correct in his conclusion that the interference between certain circuits he names is not due to inductive influence.

At the same time I conclude, from the several letters on this subject that have appeared, that it is not generally known that the observable inductive influence of one circuit upon another is not limited to yards, or even hundreds of yards, but extends to miles, scores of miles, perhaps even hundreds of miles, if only suitable means be employed.

The most striking example with which I am acquainted is one of the experiments devised and executed by Mr. A. W. Heaviside in the summer of 1886, viz., conversation per microphone and telephone carried on between two metallic circuits, consisting of squares a quarter mile on each side, a half mile between centres; shortest distance, therefore, a quarter mile between wires of a quarter mile in length. It is not the distance that is here remarkable, but the smallness of the currents in the influencing circuit. (See *Phil. Mag.*, Sept., 1886, p. 273, and Nov., 1886, Postscript to Part IV. of "Self-Induction of Wires.")

I believe that when the details of these experiments are published they may be found not uninteresting.—Yours, &c.,

February 5, 1889. OLIVER HEAVISIDE.

LIGHT WITHOUT HEAT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Owing to the frequent remarks in your editorial and other columns within the last few months upon subjects connected with the obtaining of light without its accompanying heat, and on account of the researches of Profs. Hertz and Lodge, I am induced, as a means of protection, to place before you and the public my own claims upon the subject. It was not expected that the above researches would have been discovered and brought out quite so soon, although matters have been tending in that direction for some time. My work in this field was commenced in the latter part of 1884, and has been continued in one form or another up to the present date. It is quite evident that when an electric current is passed through a filament a part of its energy appears in the form of useful light, and the remainder and larger part in the form of heat. But as light can exist and perform its various luminous, chemical and electrical effects without the aid of heat, the latter, when emitted from the filament, is a total loss of electric energy. I have at present two or three methods, with their modifications, in a more or less completed form, for overcoming this difficulty, and I hope in the near future to bring forth a lamp the illuminating parts of which can be handled with impunity, while the same is giving forth a brilliant and soft light. Perfection will be reached when the filament will remain absolutely cold while under full action. A modified source of electricity is used in some cases with these lamps as well as other sources of energy. The filaments are made in various shapes, some of them not at all resembling those we are accustomed to see, while in a few of the improved lamps none are used. The colour of the light emitted can be varied through the entire spectrum in certain forms of lamps. In his late address Prof. Brackett mentioned the idea of casting polarised rays of light upon the proper conductor, and causing an intermittency or alternation of an electric current. Now, this is almost exactly the method shown by my drawings, and described in my Papers of 1884 and 1885, except that the idea is there shown more developed. Some interesting facts in connection with this will be brought out sooner or later. A large quantity of accessory apparatus, and different methods, have been devised, which necessarily cannot be mentioned here. Finally I would like to put on record the fact that I have four distinct, and what it is thought are practical methods of generating electricity otherwise than by dynamos. The object of writing the above is as a means of protection, both from previous and from future investigators.—Yours, &c.,

Greenport, L.I., N.Y., Jan. 12, 1889. A. B. WORTH.

[Without for a moment wishing to cast the slightest doubt upon the *bonâ fides* of our correspondent, we may remind him that a mere vague declaration of this kind will scarcely enable him to "take date" over any other inventor who may happen to publish his researches before Mr. Worth is ready to do so. We should advise our correspondent to draw up a full and explicit account of his experiments, and to deposit it in a sealed envelope with some recognised scientific authority or institution.—ED. *E.*]

CONSTANT CURRENT REGULATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Pressure of business has prevented me from closely studying Mr. Edmunds's courteous reply until now. The first point in it which strikes one is that to prove the work per turn decreases as additional accumulator groups are switched on.

Digitized by Google

He says that if whilst generating 70 volts and 70 amperes through an external resistance of 1 ohm another ohm is introduced, the electromotive force immediately rises to 140 volts, the current drops to 35 amperes, and therefore the work per turn being less, the engine speeds up. But are not 70 volts by 70 amperes, and 140 volts by 35 amperes, both 4,900 watts? And if so, why does the simple ringing of the changes on volts and amperes "liberate the engine," the speed and watts remaining the same?

The secret appears to lie in the fact that with constant speed the volts will not rise from 70 to 140 because extra resistance has been put in the external circuit, but that they remain constant at 70, the current alone falling. If this be so, the watts would fall one-half, and the work per turn be halved also, and the engine consequently speed up, but whether it would double its speed appears very doubtful in practice. Seeing, however, is believing, and if Mr. Edmunds would allow me to visit his Cadogan station and see how it is done, I should feel greatly obliged.

Mr. Neville appears to have got exactly the same idea as myself on the subject, but falls foul of me for not appreciating the value of high-speed engines, which I certainly cannot allow to be the construction of my remarks.—Yours, &c.,

DOUGLAS C. BATE.

6, Derwent-grove, East Dulwich, S.E.

[Has not our correspondent overlooked the fact that the torque upon the armature varies with the current only, and is independent of the E.M.F.—ED. *E.*]

ALKALINE ACCUMULATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I did not intend to trespass on your valuable space again on this subject, but the letter of Mr. W. W. Beaumont in your last impression calls for a few remarks from me; I therefore beg the favour of your indulgence.

Your correspondent appears to have misunderstood my communication of the 23rd ult., for I venture to think I clearly stated the grounds upon which I based the claim of similarity in the batteries under notice, viz, that the three principal component parts common to all one-fluid batteries (the electrolyte and the two electrodes) are in each of these identical, these parts being an alkaline electrolyte, *compressed* silver powder, and zinc. But that there are improvements in the manner of dealing with them by Mr. Elwell's friends I freely admit, as I was in duty bound, but certainly not at the expense of explaining away the similarity I endeavoured to point out. There is one point I would like to call Mr. Beaumont's attention to, and that is, that he gives me credit for using silver powder, whereas I said I employed *compressed* silver powder, and that being so, I cannot accept his comparison of the Faure coating and subsequent compressed material as a case in point. I would like to add that although I supported the compressed powder on a silver plate, yet it was fairly coherent. I am satisfied that the result obtained by Mr. Elwell's friends is an advance on this; but the methods differ, I take it, principally in degree.

With regard to the zinc element, no doubt the use of *a* gauze is better than an ordinary zinc plate, inasmuch as it affords increased surface, and a better hold for the deposited zinc. When I read Mr. Elwell's Paper I thought *iron* gauze very unsuitable, for, unless the coating of deposited zinc keeps the electrolyte from contact with the iron, a strong local action must result, at the expense of the zinc. Doubtless, as indicated in Mr. Elwell's letter in yours of the 1st instant, this has been duly considered and provided for. I hope that a wide field may be found for the application of the alkaline accumulator, and wish Mr. Elwell all success in introducing the one he is interested in into this country.—Yours, &c.,

February 5, 1889. H. J. COATES.

HOOKHAM'S ELECTRICITY METER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I think the meter you refer to in your "Note" on the above subject is one invented by Dr. Werner Siemens. He patented a meter involving the same general principle as mine a few days after me, in March, 1887. It was not, so far as I can judge from descriptions in the technical journals, a very practical instrument, though founded on a workable principle. In his descriptions of it he made the curious mistake of stating that variations in the strength of the field did not, theoretically, affect the rate of the meter. I can hardly think he ever got to practical tests with it. If he had, practice, if not theory, would have shown him that the rate varies inversely as the field.—Yours, &c., GEORGE HOOKHAM.

Birmingham, February 5, 1889.

GLOBULAR LIGHTNING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: This evening at 7.35 p.m. a fireball about two metres in diameter fell in the direction of Stamford Hill, N. At the same time a fearful explosion took place, lasting some two seconds, and the globe of fire seemed to split into four quarters, showing a bluish fiery light. The explosion was unlike thunder, and was more like a detonation of explosives. A snowstorm of two minutes' duration ensued, leaving 1½ inches of snow on the ground; after which the atmosphere became splendidly clear. It would be interesting to know if this phenomenon has been observed by others in this neighbourhood, and under what conditions. The wind was W.N.W., sky cloudy, and the thermometer stood at 38° F.—Yours, &c.,

Listria Park, Stamford Hill, Feb. 2. ERNST FAHRIG.

THE LIGHTING OF THE CITY OF LONDON.

At a meeting of the Commissioners of Sewers of the City of London, held at the Guildhall of the said city on January 22, a report from the Streets Committee was read, of which the following is an abstract:—

"We beg to report that, having had under consideration the several references and communications made to us from time to time on the subject of electric lighting, we instructed the engineer and solicitor 'to consider and report upon the Electric Lighting Act of 1888, with power to consult with Mr. Preece thereupon, and to prepare conditions upon which proposals for lighting by electricity can be entertained, in order that thereupon the necessary steps be taken with a view to obtain offers on such conditions.'

"Having subsequently received and considered reports from the engineer, Mr. Preece, and the solicitor thereupon, we agreed that the conditions arranged the previous year with a proposed contracting company be taken as the basis of the new specification.

"That it should be obligatory on the companies with whom contracts may be entered into to lay all wires and conductors beneath the public way.

"That the City be divided into three districts, in accordance with the plan prepared by the engineer and Mr. Preece, and alternative tenders be invited for lighting the said districts and the City as a whole.

"That the main thoroughfares be primarily lighted, and be enumerated in the specification; and the companies proposing to contract be required to state the period at which the lighting of such thoroughfares will commence, and when it will be extended to the remaining streets. The Commissioners not to be bound to light the whole of the streets by electricity.

"That it be a condition of any contract that when the profits have reached a cumulative dividend of 10 per cent. the surplus be divided equally between the contracting company and the consumers.

"We referred it to the engineer and solicitor to prepare a specification, based generally on the foregoing resolutions, and having now considered the conditions of proposed contract, as prepared by them, we herewith submit the same for approval by your honourable Court, and recommend that it be referred back to us to advertise for tenders based thereupon.

"Resolved and ordered,—That the said report and proposed conditions be printed and circulated amongst the members of the Court, and the consideration thereof be adjourned until the next meeting."

The report was accompanied by the following:—

Memoranda for Supplying the City of London with Electricity.

[Abstract.]

"The main thoroughfares and public streets, &c., of the entire area of the City are to be lighted by electricity, and for convenience are divided into three districts, and contractors are at liberty to tender for either one or two of the districts or for the entire City.

"The area of the City which is to be lighted is for the purpose of the tenders divided into three districts as follows:—

"No. 1, West District, comprising the area bounded on the north by the City boundary, on the east by Aldersgate-street, St. Martin's-le-Grand, St. Paul's-churchyard (north side), Creed-lane, and St. Andrew's-hill, and thence along Queen Victoria-street to Blackfriars Bridge. On the south by the Victoria Embankment, and on the west by the City boundary.

"No. 2, Central District, comprising the area bounded on the north by the City boundary, on the east by Finsbury-pavement, Moorgate-street,

Digitized by Google

Princes-street, thence across Mansion House-street, along Walbrook and Dowgate-hill. On the south by the River Thames, and on the west by part of Upper Thames-street, St. Andrew's-hill, Creed-lane, St. Paul's-churchyard (north side), St. Martin's-le-Grand, and Aldersgate-street.

"No. 3, East District, comprising the area bounded on the north and east sides by the City boundary, on the south side by the River Thames, and on the west side by Dowgate-hill, Walbrook, Princes-street, Moorgate-street and Finsbury-pavement.

"The whole of the main thoroughfares in each district are to be lighted.

"The contractor must give a complete description of the lamps proposed to be used, and of the candle-power, both of the arc and the glow lamps. The lamps must be so placed that the light distributed over the surface of the thoroughfares shall be as uniform as possible, and those tendering will have to demonstrate upon a plan and section the relative intensity of this distribution of the electric and gas light. The standard of reference will be the illumination of a square foot of surface by a standard candle at 12·7in. distance.

"The situations of the stations for the generation of electricity, if within the City, are also to be shown, and if not within the City the points at which the main conductors enter the City. The proposed positions of the mains and service pipes or leads, both for public and private lighting, on every thoroughfare must be shown. The system by which it is proposed to supply electricity must be described.

"The contractor must give the price per annum at which each of the lamps will be lighted and maintained, according to the conditions of this specification.

"The whole of the lamps are to be efficiently lighted nightly including Sundays, from sunset to sunrise, and at such other times as the Commissioners, or their engineer, may consider necessary, on account of fogs or other emergencies. Payments will be made in respect of such extra lighting on the certificate of the engineer.

"The existing system of gas lighting must not be interfered with, but the contractor may, in certain cases, be permitted by the consent of the engineer to use any of the existing gas columns or brackets.

"If in the opinion of the Commissioners any street or portion of a district can be better lighted by glow lamps, or by arc lamps of a less intensity than that stipulated in the contract, the contractor is to change and maintain such altered lamps without further charge to the Commissioners.

"All mains and service conductors, both for public lighting and private supply, shall be laid beneath the public ways in such places and in such positions as shall be prescribed by the engineer to the Commissioners, and shall be maintained by and at the cost of the contractor in good order and condition.

"The contractor must take proper and efficient precautions for protecting from disturbance or damage all telegraph and telephone wires, and shall abide by all statutes, regulations, and enactments, and shall hold the Commissioners harmless from any damage that may arise. The contractor will be responsible for complying with all the requirements of the Postmaster-General.

"The contractor must, in all cases where practicable, and permission can be obtained, make use of the subways for laying the mains, but where no subways exist they shall be laid beneath the footways.

"To secure the due fulfilment in all respects of the preceding condition, the contractor upon signing the contract shall deposit the sum of £1,000 in respect of each district with the principal clerk to the Commissioners.

"The contractor is to supply the electricity, conductors, carbons, glasses, lamps, attendance, and everything necessary for the effectual lighting of the district during the contract period. The generating plant is to be the property of the contractor, and at the expiration or determination of the contract for public lighting all connections and fittings supplied or used exclusively for public lighting are to be removed by the contractor, and all paving, and everything else disturbed, is to be reinstated by and at the cost of the contractor.

"So far as the Commissioners are able to do so they will grant to the contractor the exclusive right of supplying electricity for private purposes within the district during the term of the contract. The contractor will be required to supply electricity to any owner or occupier of any premises within a distance of 25 yards of the mains, provided the owner or occupier enters into a fair agreement to defray or divide the cost of the service main, and to pay for the supply of the electricity. The contractor can charge the consumer for the amount of electricity supplied either by meter or by agreement.

"At the expiration or determination of the contract for public lighting the contractor is to have the right to continue to supply electricity for private purposes within the district, and to enjoy free way-leave for all mains and service leads concurrently with other parties, subject to the conditions for regulating the laying of mains and other works, and provided the contract has not been determined by the Commissioners for the following reasons:—

"1. Under the 23rd or 35th conditions.

"2. In consequence of the contractor ceasing to supply electricity for private purposes for a continuous period of one month.

"The Commissioners may at all times whilst the contract is in force test the condition and efficiency of the mains and conductors for insulation and conductivity, in such manner as they deem desirable, and the contractor must afford every facility for this purpose, must provide proper testing places and testing conveniences, and will be required to repair any defect that may be detected within a certain specified period, in default of which a penalty of £20 per day will be exacted so long as the defect continues. The Commissioners will have the power to forbid the use of any main or conductor which they may consider dangerous to public safety, and to order its removal.

"In the event of temporary failure in the electric lighting the Commissioners are to be at liberty to light the streets by gas or any other method, and all expenses consequent upon their so doing shall be paid by the contractor. The contractor will be liable to a penalty of forty shillings per lamp for any and every instance of failure or default in supplying light in any public lamp for any period exceeding five minutes.

"If the profits arising from this contract exceed a cumulative dividend of 10 per cent. per annum upon the capital invested the excess is to be divided equally between the contractor and the consumer. In other words, the contractor will not be entitled to pay a dividend of over 10 per cent. per annum, calculated from the commencement of contract, unless at the same time the cost of the supply of the electricity to the consumer is reduced at the rate of one halfpenny per unit, as per schedule, for each 1 per cent. added to the dividend.

"The duration of the contract for public lighting is for a period of twenty-one years from the completion of the lighting in all the streets, and shall be subject to determination by the Commissioners if the lighting upon the certificate of their engineer is inadequate or inefficient, or if the plant and system have not been maintained in thorough efficiency, any dispute as to the inadequacy or insufficiency of the lighting, and of the maintenance of the system, to be referred to arbitration.

"The Commissioners shall have the option, by giving three months' notice in writing, prior to the expiration of the term of twenty-one years, to renew the contract for public lighting for a further period of seven years, and so on from seven years to seven years by giving a similar notice. Each renewal to be subject to any revision of terms which the success of the contractor, or the improvements introduced in supply or lighting may suggest.

"In the event of the contractor failing, after receipt of due and formal notice at three separate times, with proper intervals, to comply with the conditions of the contract, to maintain the plant, mains, and conductors in proper order, and to provide sufficient electricity, the Commissioners shall have an immediate power to determine the contract as to public lighting, and to order the removal of the mains and conductors, whether used for private or public lighting.

"Power is to be reserved to the Commissioners to acquire the undertaking and works by purchase at the end of twenty-one years, or each succeeding seven years, on giving six months' notice, in accordance with Section 2 of Electric Lighting Act, 1888."

ELECTRIC LIGHTING IN KENSINGTON.

The following is the important part of the report of the Special Committee of the Kensington Vestry appointed to consider matters relating to electric lighting:—

Your Committee, after giving their best attention to the various important and difficult questions raised by the applications of the several electric lighting companies for Licences and Provisional Orders, beg to report as follows for the consideration and approval of the Vestry:—

In the early part of the year 1888 notices were served by the following companies of their intention to apply for Licences to light various portions of the parish of St. Mary Abbotts, Kensington, viz.:—(*a*) Notting Hill Electric Lighting Company (Limited); (*b*) Kensington Court Electric Lighting Company (Limited); (*c*) House-to-House Electric Light Supply Company (Limited),

and in the month of June last notices of intention to apply for Provisional Orders for the same purpose were served by the following companies, viz.:—

1. London Electric Supply Corporation (Limited).
2. Metropolitan Electric Supply Company (Limited).
3. Notting Hill Electric Lighting Company (Limited).
4. Kensington and Knightsbridge Electric Lighting Company (Limited).
5. Chelsea Electricity Supply Company (Limited).
6. House-to-House Electric Supply Company (Limited).

The following two companies gave notice of their intention to apply for Provisional Orders, but have not proceeded further with them:—

Kensington Court Electric Lighting Company (Limited).
West Middlesex Electric Lighting Company (Limited).

1.—Responsibility and Pecuniary Status.

Your committee upon the whole have come to the conclusion that there is no sufficient reason for excluding any one of the companies from Kensington, on account of its want of pecuniary status, or of probable capacity to carry out its undertaking, and therefore

Recommend—

That none of the companies should be excluded on the above ground.

2.—Licences and Provisional Orders Compared.

Another point which has engaged the attention of the committee has been the relative advantages of a system of Licences and of Provisional Orders. Their consideration of this matter has been rendered comparatively easy by the recently-announced intention of the Board of Trade not to grant Licences for any large or important area. Unless, therefore, the Vestry should deem it advisable to make experiments in small areas, instead of assigning the whole or the larger part of the parish to some of the companies now seeking for Provisional Orders, your committee feel that the Vestry have no alternative but to refuse their consent to all the applications for Licences, and to deal with the applications for Provisional Orders only. Your Committee fear that some at least of the companies would not be induced to incur the necessary expenditure upon the security of a Licence, and are unwilling to refuse to those companies who have incurred, or are incurring, considerable expenditure, that larger concession which

Digitized by Google

they would have to grant to other companies if they are to be induced to take up the work ; they therefore

Recommend—

That, with the exceptions hereinafter mentioned, the Vestry refuse consent to all Licenses applied for by the above.

3.—Competition v. Monopoly.

Your Committee have been more particularly occupied in the consideration of the question how they can combine the benefits of competition with those of a well-regulated monopoly. To those who remember the inconvenience which arose to the public from the frequent interference with the streets by rival gas companies, the advantage of having the electric light supplied by only one company will be apparent ; whilst to those who have suffered from the high charges and insufficient service of a company with a monopoly, the advantage of competition is self-evident.

Your Committee would observe that it is enacted by the Electric Lighting Act, 1888, sec. 1, that "the grant of authority to any undertakers to supply electricity within any area, whether granted by Licence or by means of a Provisional Order, shall not in any way hinder or restrict the granting of a Licence or Provisional Order to the local authority, or to any other company or person within the same area." It is clear, then, that no legal monopoly is given to any company by the granting to it alone in the first instance the right, by Provisional Order, of lighting any part of the parish.

Your Committee are of opinion, upon the whole, that considering the right the Vestry will have, if circumstances should require it, to obtain themselves, or to consent to other companies obtaining, Provisional Orders to light the same districts as other companies, it is better in the first instance to assign a given portion of the parish to only one company. They thus gain a comparative amount of freedom from disturbance to the streets, and avoid the unnecessary reduplication of mains in streets and consequent waste of capital. As each company will know that its immunity from direct competition in its own district depends upon its good conduct and the reasonable nature of its service and charges, it will have, in the opinion of your committee, sufficient inducement to carry on its undertaking efficiently and economically, and thereby the parish will get the advantage of a potential competition. It may, however, be a question whether the Board of Trade should not in each Provisional Order place a larger district than that primarily conceded to each company in a separate schedule, with a provision that the company should not supply electricity in such extended district until after the Vestry has at two successive meetings (after certain specified notice to the company in whose original district such area was included) passed resolutions that it is desirable there should be a second company authorised to supply electricity in such extended district. Your committee propose, with your approval, to request the Board of Trade to consider the expediency of such a provision, as rendering the potential competition a more powerful inducement to efficiency and low charges ; they therefore

Recommend—

(*a*) That in the first instance only one company have any portion of the parish conceded to it by Provisional Order for lighting purposes ; (*b*) that the Board of Trade be requested to arrange for an extended area of supply being included in each Provisional Order, subject to such conditions as are above suggested ; (*c*) that such last-mentioned area should in each case include all that portion of the parish applied for by each company, but which is not comprised in the area to be assigned to the company in the first instance.

4.—Districting of Companies.

Assuming, therefore, that the Vestry agree with your Committee that, upon the whole, it is better to assign in the first instance a separate district to an individual Company, your Committee

Recommend—

That the following companies (some particulars of each of which are given) should have the district allotted to it which is described.

(1) London Electric Supply Corporation (Limited).

This Company includes in its Provisional Order more than half the Metropolis, and your Committee do not therefore consider themselves justified in assigning to it any part of the parish which is likely to make an immediate demand for electricity.

At an interview with one of the directors of the company, your Committee understood that the company would not be likely to accept the above, which was the only proposal the Committee felt justified in making, and therefore further

Recommend—

That, in the event of its not being finally accepted by them, District No. 1 be added to that offered to one of the other companies.

(2) Metropolitan Electric Supply Company (Limited).

This company is also a large and important one. It proposes to supply the electric light in a considerable part of London, and your committee therefore are unable to say how much of the £500,000 already subscribed is already forestalled for other districts.

(3) Notting Hill Electric Lighting Company (Limited).

This company has not yet called up any capital or constructed any works, but your Committee are satisfied that it is a *bonâ fide* concern, well supported both by engineering talent and by gentlemen of local influence, and believe that if a Provisional Order is granted the company will at once apply itself to carrying out works in the district assigned to it.

(4) The Kensington and Knightsbridge Electric Lighting Company (Limited).

This company already holds a Board of Trade License for the Kensington Court district and adjoining parts, and has raised and expended a considerable amount of money (shown in the appendix) in constructing central stations, the one at Kensington Court having been for some time in operation, and the other in Chapel-place, Brompton-road, being in course of construction. From these two centres the company can conveniently and economically light the area which it is proposed to include in their Provisional Order, and which contains within it the smaller district, now successfully lighted by the company under their existing License, and another district which your Vestry have consented to their obtaining a License to supply, pending the grant of the Provisional Order and its confirmation by Parliament, which, when granted, will supersede the two Licenses.

(5) Chelsea Electricity Supply Company (Limited).

This company obtained a Provisional Order in 1886 for the supply of electricity in a considerable area of Chelsea. Some delay has arisen in the construction of their works, which, however, are now being carried out. The contract for the construction of the works binds the contractors, your Committee are told, to an early completion under heavy penalties, and the company state that they will shortly be in a position to supply the electric light.

(6) House-to-House Electric Light Supply Company (Limited).

This company is now in a position to supply a large number of lights, whilst its works are so constructed as to be capable of extension with a view to generate a much larger amount of electricity when the demand requires it.

With regard to the three last-mentioned districts (4, 5, and 6), which together make up the whole of the parish south of the Kensington-road, it will be observed that the line of railway from High-street, Kensington Station, to South Kensington Station has been adopted as the dividing line, as it is believed that the railway tunnel affords facilities for conducting electric mains along it which are likely to be made use of by some, if not all, the companies, to the relief of the public streets.

5.—Provisions for Safety.

Whilst your committee have not overlooked this most important matter, they do not consider it necessary to make a special report to the Vestry upon the provisions which should be adopted to prevent accidents, as they believe such provisions will be more effectually secured by the action of the Board of Trade. They therefore

Recommend—

That the Board of Trade be requested to make such provisions under this head as they may think fit.

6.—Overhead Wires.

As regards overhead wires, your Committee

Recommend—

That no company acquiring any powers in Kensington shall be at liberty to carry any wires otherwise than under ground, and that all wires previously placed overhead by any such company shall, on any License or Provisional Order taking effect, be removed and placed underground.

All the companies practically agree to this requirement.

7.—Mode of Laying Wires.

Your committee are anxious that some uniform system of laying down wires should be adopted by all the companies serving any part of the parish of Kensington. They are not prepared without further consideration to advise the Vestry what such system should be, but

Recommend—

That the proper objections should be made to the Provisional Orders, with the view to securing (*a*) the adoption of the best mode of laying down electric mains, wires, and lines ; (*b*) that all work shall be done to the satisfaction of the Vestry ; (*c*) That the Vestry, should they so determine, shall have power to lay down culverts or channels at their own expense, and to require the companies to use the same, paying a reasonable rent for the accommodation.

8.—Generating and other Stations in Parish.

As several of the companies will have works for generating and storing electricity in the parish, your Committee consider that the Vestry should have a right of veto upon their being placed in positions or otherwise so constructed or used as to be detrimental to the neighbourhood. In particular they would urge that no engines of a non-condensing character be constructed, and that the best Welsh or other smokeless coal shall always be used in the furnaces, and generally that the works in the parish be constructed and managed to the satisfaction of the Vestry ; they, therefore,

Recommend—

That the Board of Trade be asked to insert clauses to this effect in the Provisional Orders.

9.—System of Charging ; and 10.—Maximum Price.

The system of charging for electricity is very various in the different Orders, and will require revision.

The Board of Trade unit of 1,000 amperes* has been changed in some of them to one of 10,000 amperes, without, apparently, sufficient reason, unless it have the advantage of facilitating the working of a sliding scale hereinafter referred to. Your committee therefore

Recommend—

That this matter, with various other details connected therewith, be left to your Committee, who would raise all necessary objections, so as to enable them afterwards to settle the clauses by conference with the companies, or, if necessary, by referring any difference to the Board of Trade.

[*We were under the impression that the Board of Trade unit is expressed in terms of watt-hours.—Ed. *E.*]

Digitized by Google

11.—Revision of Charges and Sliding Scale.

One company (the House-to-House Company) proposes a provision for the revision of charges at the end of seven years, and the establishment of a sliding scale of price and dividend analagous to that adopted of late years by Parliament in the case of Gas Companies. The following is a copy of the provision:—"At the expiry of the first seven years of this Order the undertakers agree to the fixing by arbitration in the usual way of a standard price to be charged by the undertakers for electricity on the basis of 10 per cent. per annum of clear profits, provided that the undertakers may increase or diminish such standard price, subject to an increase or decrease in the standard rate of dividend (10 per cent.), to be calculated as follows:—For every penny or part of a penny charged in excess or diminution of such standard price in any year, the standard rate of dividend shall for such year be reduced or increased by five shillings in the hun ired pounds per annum.'

A somewhat similar provision is contained in the Notting Hill Company's provisional Order.

Without committing themselves to the words of either of these proposed provisions, your committee believe that no greater inducement to economy in working could be found, and that thereby the consumer will have as good an opportunity of an early reduction in price as would be found either in any other statutory provision, or in the direct competition of two companies in the same area, and

Recommend—

That some such provision should be accepted as regards the above company, and as regards other companies, inserted in their Provisional Orders.

12.—Appropriation of Separate Capital.

In order to secure the proper working of the sliding scale, it is necessary that the amount of capital properly spent in accommodating the district should be correctly ascertained, and in doing this, with the existing knowledge on the subject, there must be considerable difficulty. Some of the Provisional Orders are altogether silent upon the subject of capital: your committee therefore

Recommend—

That the Board of Trade should be urged to insert clauses in all the orders as to the capital to be specially appropriated in supplying Kensington with electricity, leaving to the committee the details of the objec tions which should be raised under this head.

13.—Purchase of Undertaking.

Section 2 of the Electric Lighting Act of 1888 provides that the local authority shall have an option of purchasing the undertaking after the expiration of forty-two years, or such shorter period as is specified in the Act confirming the Provisional Order, from the date of passing such Act, and also after the expiration of every subsequent period of ten years, or lesser period specified in the Provisional Order. Your Committee think that a shorter period than forty-two years should be inserted in the several Provisional Orders, and have reason to believe that all the companies would consent to the first period being twenty-one years, and the subsequent periods seven years, and they

Recommend—

That your committee should be authorised to endeavour to obtain this concession as a condition of the Vestry giving its approval to the Provisional Order.

Temporary Licences.

In the event of the system of districting recommended by your Committee being approved by the Vestry, it would seem desirable, with a view to bringing the electric light into early use, that the Vestry should consent to a License being granted by the Board of Trade to such of the abovementioned companies as may be ready to supply electricity within the next few months in the areas which it is contemplated they should light under the Provisional Orders. If any such company would adopt the terms of the License granted to the Kensington Court Company in October, 1887 *(mutatis mutandis)* as the terms of such a temporary License, your committee

Recommend—

That the Vestry should give its consent for grant of such License by the Board of Trade, upon the condition that such License should be superseded by the Provisional Order when confirmed by Parliament, and if not so confirmed, should not last for more than a year or eighteen months from the date of such License.

(Signed) Jno. Jordan, Chairman.

The report was unanimously adopted in a full Vestry.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

Note.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

January 7, 1889.

266. Thomas Boothby. London. A bracket to support the ear-piece of telephones and other instruments.

276. C. Grant. Glasgow. Portable dynamo-electric signalling apparatus for military and other purposes.

278. G. Wehr. London. Lightning conductor for telegraphic purposes.

282. F. Coates. London. Improvements in conduits for electric mains.

292. P. F. Luck. London. Improvements in electric alarm thermometers.

January 8, 1889.

320. W. P. Kookogey. London. Improved methods of preparing solution compounds for galvanic batteries.

342. W. M. Mordey. London. Improvements in or relating to the regulation of dynamo-electric machines.

361. H. H. Lake. London. Improved methods of and apparatus for welding, forging and otherwise working metals by the aid of electricity (E. Thomson, United States).

362. H. H. Lake. London. Improved methods of and apparatus for welding, shaping and otherwise working metals by the aid of electricity (E. Thomson, United States).

377. H. H. Lake. London. Improvements relating to the riveting of metal plates and other objects by the aid of electricity (E. Thomson, United States).

January 9, 1889.

COMPANIES' MEETINGS & REPORTS.

The Cuba Submarine Telegraph Company (Limited).

The thirty-fifth ordinary general meeting of the shareholders in this Company was held at the offices of the Company, 58, Old Broad-street, E.C., on Wednesday last. Mr. Joaquin de Mancha presided.

The SECRETARY (Mr. James Scott) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen, it is always a pleasant duty to meet our fellow-shareholders on these occasions, particularly when we can present so good an account, which I think you will all be satisfied with. You will remember that we carried from the last year's account £1,195. To that we have been able to add out of the six months' working, which is the worst six months of the year, the sum of £20,708, which I think is very

Digitized by Google

satisfactory, our messages having increased during that time by 3,440. Out of that we now propose, with your permission, to declare a dividend on the Preference shares at the rate of 10 per cent., and on the Ordinary shares at the rate of 9 per cent. per annum. I think that, having regard to the difficult nature of the business in which we are engaged, that is a gratifying result. I can only hope that we shall continue to be able to pay the same dividend in the future. You are aware that the French cable which we have been threatened with so long has at length been laid from Venezuela to San Domingo, Hayti, and from there to Cuba. We did all that we could to see that our rights were not trenched upon. Mr. Scott went to Madrid to our agents there, and gave them all the requisite information and instruction to protect your interests. Mr. Keith, our manager in Cuba, also did all he could by putting our case properly before the Government officials to see that we were not at all prejudiced. I hope that nothing will occur to injure us, and that we shall go on working as prosperously as we have hitherto done. The only other matter to which I would call your attention is what we say about the Cienfuegos-Batabano section of our cable. Cables, like ourselves, do not last for ever. It has been laid a long time, and there are occasionally small interruptions in it. Mr. Keith having been over here, we engaged a steamer which is going to take out cable sufficient for any repairs that may be required, so that the traffic may not be delayed, and we hope that with the appliances we have sent him he will be able to keep things in perfect order. If by any chance there should be a greater injury to the cable than we have as yet experienced or anticipated perhaps we may have to duplicate it. That is why we are always so careful to keep the reserve fund as strong as possible. It is a security both to the preference and the ordinary shareholders, and if we had to come upon our earnings for anything of that kind we should have to reduce the dividend. I hope, therefore, you will approve of our policy in always keeping a good fund in hand to meet any repairs that may be required, and I think when you look at the amount which our reserve fund has grown to—£84,000—I think you need not fear that there is not enough not only to repair any portion of our cable, but to leave sufficient in hand for any future emergencies. He concluded by moving the adoption of the report and accounts.

Mr. ALEXANDER F. LOW seconded the resolution.

Mr. KEENLYSIDE suggested that as the Company earned 15 per cent., out of which 6 per cent. went to the reserve fund, they should be content with putting aside only 5 per cent., and thus allow 1 per cent. more to be divided among the shareholders.

Mr. COCHRAN hoped that the body of the shareholders would endorse with unqualified expressions his approval of the policy of the Board in building up a good reserve fund. It was the great security of the Company against future contingencies.

The CHAIRMAN said that his own feeling in the matter was that he would like to see the fund up to £100,000. Then they might feel quite at ease, for whatever occurred they would be in a position to lay the cables afresh.

The resolution was carried unanimously.

Subsequently a resolution was carried declaring the dividends recommended, namely, at the rate of 10 per cent. per annum on the Preference, and 9 per cent. per annum on the Ordinary shares of the Company.

The CHAIRMAN said he would be sorry if the shareholders parted without giving an expression of their approval of the zealous manner in which the staff of the Company had performed their duties. He always found that their *employés*, both here and abroad, displayed great intelligence and diligence in their work, and he was sure it would be a great source of satisfaction to them to hear that the shareholders appreciated that fact.

Mr. COCHRANE seconded the motion, which was unanimously carried.

The SECRETARY briefly returned thanks.

On the motion of Mr. SQUIRE, seconded by Mr. GREENWOOD, a cordial vote of thanks was accorded to the Chairman and Directors, who, Mr. Greenwood remarked, were the right men in the right place.

The CHAIRMAN having acknowledged the compliment, the proceedings terminated.

The German Union Telegraph and Trust Company (Limited).

The eighteenth and final ordinary general meeting of the shareholders of this Company was held at Winchester House, Old Broad-street, on Wednesday last, Sir James Anderson presiding.

The SECRETARY (Mr. Wm. Payton) read the notice convening the meeting and the minutes of the last ordinary and extraordinary general meetings, which were confirmed by the present meeting and signed by the Chairman as correctly entered.

The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN, in moving their adoption, said that he confessed to some disappointment in meeting the shareholders on that occasion, inasmuch as when he last addressed them he had held out hopes of their getting very nearly par for their shares, the calculation they had made being within 1s. or 1s. 6d. of their full value; but since that time there had been a cable broken which it had cost the Company no less than £7,684 to repair. That would amount to a charge of 6s. 8d. on each original share. The money sent over here was sent in marks, and the exchange was something like 5¼d. against the Company, so that the money that would be posted to them that day would be £7. 6s., the total sum they would ultimately receive for their shares being about £9. 10s.

Mr. HERMANN GUSTAV ERICHSEN seconded the motion, which was carried unanimously.

An extraordinary meeting was subsequently held, at which the special resolutions passed on the 22nd January, requiring the Company to be wound up voluntarily, and appointing Sir James Anderson and Mr. Wm. Payton liquidators, were confirmed.

Mr. LOWENTHAL proposed a vote of thanks to the Chairman and Directors, which was seconded by Mr. GRIFFITH, and cordially agreed to.

The CHAIRMAN returned thanks, expressing his regret that the Company was broken up after so prosperous and promising a career.

Anglo-American Telegraph Company (Limited).

The ordinary general half-yearly meeting of the proprietors of this Company was held at Winchester House, 50, Old Broad-street, on Friday, the 1st inst., the Right Hon. Viscount Monck presiding.

The SECRETARY (Mr. T. H. Wells) read the notice convening the meeting and the minutes of the last meeting, the latter being confirmed and signed by the Chairman as correctly entered.

The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen, the report being taken as read, I desire, in the first place, to express my acknowledgments to the stockholders generally for excusing my attendance at the last half-yearly meeting, and to my noble friend on my left (the Marquis of Tweeddale) for the kindness he showed in undertaking my duties on that occasion. At the moment I was affected by an attack of illness which was neither serious nor dangerous in itself, and it has passed away without leaving any serious trace behind it, but it had effects at the time which thoroughly disqualified me from taking my place as Chairman of the general meeting. I think, however, you will agree with me, that so far as your interests were concerned very little apology for my absence is necessary. The manner in which my noble friend discharged the duties, which he so kindly undertook at so short notice, left nothing to be desired on your part, and, to say the least of it, prevented any mischief that might have occurred owing to my absence. Gentlemen, on these occasions the topics for discussion are not very extensive. They lie within a narrow range, and when you discuss the condition of your plant, the expense of maintaining and repairing it, the revenue which you have derived from its working, and the prospects of the Company, you have nearly exhausted the category of subjects upon which it is necessary to comment. In proposing that the report and accounts be adopted, I would say a few words on each of these matters. With regard to your plant, you will observe from the report that, with comparatively trifling exceptions on the other side of the Atlantic, it is in very good condition. We have had, as you have heard, a good deal of repairs during the past half year. There are one or two observations which I should like to make connected with them, and which I think are not on the whole unsatisfactory. In the first place those repairs have been done entirely by your own steamer. This gives you the advantage of having your repairs done at first cost, and it further demonstrates the necessity or advisability which exists for keeping your own repairing ship. Your deep sea cables have been all in good order except the cable of 1869—the original French cable—upon which we have had very considerable repairs to effect. We picked it up in two or three places at a depth of nearly 2,000 fathoms, and successfully repaired it. It is now in its twentieth year. I confess it makes me feel rather old to find my bantling so nearly approaching its majority; but I am glad to say it is doing very good business, and we have been able to put it in thorough working order this year. So much with regard to the repairs and condition of your plant. With respect to the expenses, which have been incurred independently, of course, of repairs and renewal of cable, there is not much to be said. During the half year we have attended most carefully to the expenditure, and endeavoured to reduce it as much as possible; but if you will take the trouble of comparing two or three of the annual reports, and looking at the details of the expenses which are given at the end of them, I think you will find that there is a very small portion of the expenditure over which the Directors can exercise any great control. You must pay your wages, you must feed your people, and you must maintain your lines, upon which the greatest expense generally occurs. I do not think, however, that you will find on comparison that there is very much difference between the last few half years in the items of expenditure. As a matter of fact, the outlay for the present half year is, it appears on the face of it, £1,000 less than it was in the corresponding half of last year; and when you come to look into it you will find that there is some extraordinary expense in that half year which really takes the matter out of the category of comparison. There is an item in the expenditure to which I would draw your attention, because it puts us in a position of safety for the future, and that is the estimate of the amount which the French law suit will cost us. We have debited ourselves with £2.000 for the costs of that, and we believe that is an ample estimate of the amount they ought to come to, and therefore the item will not appear again in your accounts. With regard to our income and prospects, we meet to-day under conditions, I am happy to say, which, if they do not give rise to any effusive jubilation, are at all events more satisfactory than they were at our recent meetings. It will be in your recollection that in July, 1887, your Directors announced that their policy was to adopt a very small tariff, not as a hostile measure, although to a certain extent there must be some hostility wherever there is competition, but to test by experiment what tariff was the lowest that we could give the public consistently with leaving to ourselves a moderate return. We announced at the time that we intended to adopt the 6d. rate, and to maintain it for a long enough period to give us experience of its effects. I may say—and I have no doubt that most of the shareholders are aware of the fact—that the receipts at different seasons of the year vary considerably, and therefore an experiment made in the autumn would not be a sure guide with reference to the whole year. Well, we maintained the 6d. tariff for more than one year, and I think we proved to the thorough dissatisfaction of every one concerned that in the present condition of Atlantic tele-

Digitized by Google

graphy a 6d. tariff would not pay any one. The result of that was, as you are aware, that we increased the rate to 1s. a word. The experience that we have had of that rate, for the reasons that I have mentioned, has not been long enough to enable us to decide whether it is a satisfactory one or not; but up to this time it has not been unsatisfactory. I trust that the same reasonable conduct which induced the different companies engaged in telegraphy in the Atlantic to raise the tariff to 1s. will also induce them to go further if it becomes absolutely necessary, in order to get to the limit at which it will pay; but, as I have said, the period during which the 1s. tariff has been in operation has been too short to enable us to arrive at a definitive decision as to the propriety of maintaining it at that figure. But I hope that we may be able, by the exercise of moderation and forbearance towards our adversaries, to fix ultimately on a tariff which, without bringing you in such large returns as to induce further competition, will give you a moderate and remunerative return for the money you have invested in the concern. With these observations I beg leave to move—

"*That the report of the Directors, and the accompanying statement of accounts to the 31st Dec., 1888, submitted to this meeting, be and the same are hereby received and adopted.*"

The MARQUIS OF TWEEDDALE seconded the motion.

Mr. SMITH (York) congratulated the Directors on the improved condition of the Company and its prospects, and said it would be a source of satisfaction to the shareholders if the Chairman would state how they stood in reference to the litigation still pending between the Company and the Paris and New York Telegraph Company. He had been connected with the Company a great many years, and the present was the best report he had seen for four or five years.

Mr. GUESDON thought it must be very encouraging to all interested in cable enterprise to think that the Company's oldest cable was in such good condition. When they took into account the very great improvement that had been recently effected in the manufacture of cables, he thought that the life of a cable now might be calculated on with a great deal more confidence than it could have been a few years ago. It was a very agreeable fact to find that the destructive competition among the rival companies had terminated. He looked upon the 1s. tariff with great favour, and he hoped that when the agreement between them terminated 12 months hence some understanding would be arrived at whereby the 1s. tariff would be maintained and unity established among the companies. The Directors had had the firmness to refuse to pay a dividend during the time that they had carried on the "war," and had built up a reserve fund which greatly strengthened the position of the Company. Another fact which he thought the Directors would have realised by this time was that it was necessary, in order to shut out unhealthy competition, to be satisfied with moderate profits. His hope was that by the expiration of the 12 months, the various Atlantic telegraph companies would come to some permanent arrangement by which competition would be done away with.

Mr. CHIPPERFIELD asked whether there was now a joint purse with all or with how many of the cable companies; whether it was not the Anglo-American Company that gratuitously initiated the charge of 6d.; how soon the other companies followed suit, and who suggested a return from 6d. to the 1s. tariff? He thought the subjects mentioned by the Chairman as coming properly under discussion among the shareholders were very unimportant compared with the question of tariff charged. When they adopted the 6d. charge he felt that it was a most suicidal course, and he thought that the result proved it to have been so. He could not conceive how gentlemen with the experience of the Board could have done such a foolish thing, and their conduct in that matter, if they gratuitously took the initiative, as he assumed they did, deserved severe condemnation.

Mr. WOOD expressed his regret that the 6d. rate, which he thought would be the rate of the future, could not be maintained. It ought to be their aim to keep down the tariff as low as they possibly could, so as not to make enemies of the telegraphing public, which they had done for a long course of years. He desired to ask the Directors what they thought would be the "life" of a cable, and from what they had seen whether it was likely that the old cable, which had just been repaired, would serve other five or eight years?

Mr. JACKSON said that paragraph 7 of the report was to him the most emphatic and conclusive evidence that the policy of the Board was the right one. The statement that peace had been established among all the companies doing telegraph business across the Atlantic was most important to the shareholders, and he wished to accentuate the hope of Mr. Guesdon that at the end of twelve months every courtesy would be extended to their rivals, with the object of bringing about permanent unity among the companies. As to the remark of the gentleman who attacked the Board for taking the initiative in adopting the 6d. tariff, he must remind the meeting that the Directors appealed to the shareholders and got their universal assent to that policy. He unhesitatingly said that for the last five years they had not been in so sound, satisfactory, and promising a condition.

After some remarks from Mr. PICTON and Mr. HUMPHRIES,

The CHAIRMAN, in reply, said: I do not think there has been any question raised to require a very long answer from me. Mr. Chipperfield denounced the conduct of the Directors in very unmeasured language, and said we could not have had brains to do such a thing as to adopt the 6d. tariff. Mr. Chipperfield looks old enough to recollect the reduction of the postage rate to 1d., and he must remember that when the postage was higher the Post Office did not pay. When it was reduced to 1d. after a few years the Post Office became a source of revenue to the State, and is now a very large contributor to the annual revenue of the country. When we are told that the application of the same principle to your business was an act of folly we may fairly quote that instance against Mr. Chipperfield's argument. At all events, I do not think that the observations of the honourable gentleman carried the meeting with him. I was asked a question with reference to the probable life of the 1869 cable. All I can say is that I hope it will last for a very considerable time; and I may tell you that wherever the cable has been picked up with favourable conditions at the bottom of the sea it was as good as it was on the day when it was laid. But there are certain points at which the conditions of the bottom of the sea are very unfavourable to a cable, and they caused a good deal of friction, which destroyed the cable in certain places. But the great body of the cable is, I believe, as good as it was the day it was laid. The experience we have had during the last few years has shown that applied science has been brought to such perfection that you can really pick up a cable at a depth of three miles as easily as you could pick it up from this floor and effect repairs. So far as we can judge, this cable may last for a great many years yet. As far as I could understand Mr. Humphries, he wished us to issue Four per Cent. Debentures and buy up our own stock. I need not tell you that that would be a grossly illegal act. The only other remark to which I think it necessary to allude is that made by Mr. Smith with reference to the law suit we are carrying on in France, and if you will allow me I will ask our law agent to explain how that stands.

The SOLICITOR (Mr. Burt) said that the meeting would remember that their action against the Paris and New York Company was commenced in the Tribunal of Commerce of Paris. In that court the Company obtained a satisfactory judgment. The defendants appealed from it to the Court of Appeal in Paris, which, while expressing itself, as it appeared to him, in favour of the Company's claim doubted whether the Tribunal of Commerce had jurisdiction to give the judgment which was given. In the concession held by the French Company it was stipulated that any question arising between the Government and the holders of the concession should be decided not by the ordinary law courts but administratively by the Conseil de Prefecture de la Seine with the right of appeal from that Council to the Council of State. The Court of Appeal said: "Before we decide this question you must go to the Conseil de Prefecture de la Seine in order that they may, in accordance with the terms of the concesssion, determine what was the legal value of the letter written by the French

Minister of Posts and Telegraphs to the Paris and New York Telegraph Company, on which they broke the contract." That reference to the Conseil de Prefecture de la Seine was now pending, and was arranged to be heard on the 26th of this month. He could not hold out the hope that that would be an end of the question. Whichever side lost would probably appeal to the Council of State. On the administrative question they would have to go back to the Court of Appeal, and then they would decide between them. He was sorry that that should be the case. £2,000 was the estimate of the proportion of this Company's expenses in the French Courts, and he might say that the expenses in France were quite equal, if not superior, to those in the English tribunals. In further reply to Mr. Smith, of York, he added that it was not possible to obtain a deposit for the amount of the damages which were alleged. They would have had to give security for the return of the money, together with compensation for all the loss which the other side had sustained, and they were advised by the ablest lawyers in Paris that it was much wiser on that account not to ask for the deposit.

The resolution was then put to the meeting, and carried unanimously.

Sir James Anderson and Mr. Wm. S. Cunard, the retiring Directors, were re-elected, as were also the auditors, Mr. Joshua Dean and Mr. Francis Glass.

Mr. CHIPPERFIELD proposed, and Mr. GUESDON seconded, a vote of thanks to the Chairman, which was cordially passed, and

The CHAIRMAN having briefly acknowledged the compliment, the proceedings terminated.

Taunton Electric Lighting Company.

The second annual meeting of the shareholders in this Company was held at the Castle Hotel, Taunton, on Monday evening, under the presidency of Mr. W. H. Fowler, the Chairman of the Company.

The CHAIRMAN moved the adoption of the report of the directors (which appeared in our last issue). He said it was a very satisfactory thing that at this end of their second year they were able to pay an increased dividend, and at the same time to make proper provision for depreciation of plant, and for any extraordinary expenditure that might come upon them. They had carried forward a sum of £207. 13s. 7d., and as the machinery was kept in its highest efficiency he thought they could consider they were fully justified in paying an increased dividend. At the same time it was absolutely necessary to enlarge their plant, and they would be unable to do so unless they had further help from the general public. If others were prepared to back him up, he would put a further sum of £500 in the Company, because he was fully satisfied that the thing would be a success provided they made it large enough to meet the demands of the general public.

Mr. O. E. LANCE seconded the adoption of the report.

Mr. H. G. MASSINGHAM, the managing director, said the revenue had increased by 45 per cent. during the past year, and he thought there was every probability that next year they would earn a dividend of not less than 7 per cent., for at present they had a large number of customers waiting whom they were unable to supply until they had additional plant. Whereas two years ago they commenced with one dynamo, they now possessed six. He believed it was the most successful installation in England, and they had been very fortunate in not having any accidents.

Mr. POTTER, a director, stated that the success of this Company was unprecedented in the history of electric lighting in England.

The retiring directors and auditor were re-elected and thanked for their services, and a vote of thanks to the chairman terminated the proceedings.

The India Rubber, Gutta Percha and Telegraph Works Company (Limited).

Report of the Directors for the year ended December 31, 1888, to be presented to the twenty-fifth ordinary general meeting of the shareholders, to be held at the Cannon-street Hotel, London, on Thursday, the 14th inst., at half-past one o'clock :—

The accounts show the net profit for the past year to be £57,157. 14s. 2d. Adding £9,530. 3s. 5d. brought forward, and deducting £20,800 interim dividend paid in July, there remains a disposable balance of £45,887. 17s. 7d. The Directors recommend the distribution of a dividend of 10s. per share, free of income tax, amounting to £20,800, making, with the interim dividend, a total payment for the year of 10 per cent., and leaving £25,087. 17s. 7d. to be carried forward. The Company's general business continues to increase ; but competition is as keen as ever, and only a low rate of profit can be made. The submarine cable work of the year has consisted of several items of small amount. The works are now occupied in the manufacture of about 800 miles for the Eastern and South African Telegraph Company, to be laid in May on the West Coast of Africa, in extension of the West African Telegraph Company's cables manufactured and laid by this Company. The Company's works and machinery are in efficient working order. Mr. Scott and Mr. Henderson, the Directors retiring by rotation, offer themselves for re-election. The auditor, Mr. Weise, retires, and is re-eligible.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended February 1st amounted to £4,796.

CROMPTON AND CO.—The directors have declared an interim dividend of 7 per cent. per annum upon the Preference shares of the company for the five months ended 31st December last ; they have also decided to pay at the same time the 4 per cent. interest to same date upon the amounts paid in full in advance of calls.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of January was 3,922, estimated to produce £3,100, against 4,064 messages, producing £3,366 in the corresponding month of last year. The traffic receipts for the month of October, estimated at £3,300, realised £3,316.

DIRECT SPANISH TELEGRAPH COMPANY.—The traffic receipts of this company for the month of January were £1,880, as compared with £1,943 last year.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of January were £65,835, as compared with £56,164 for the same period last year, or an increase of £9,671.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of January were £41,820, as against £39,878 for the same period last year.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this company are as follows :—January, 1889, £22,400 ; corresponding month, 1888, £21,400 ; corresponding month, 1887, £20,400.

LONDON AND PROVINCIAL ELECTRIC LIGHTING AND POWER GENERATING COMPANY.—Mr. Justice Chitty has appointed Mr. Lionel H. Lemon, chartered accountant, official liquidator of this company, in place of Mr. W. Lott Grimwade.

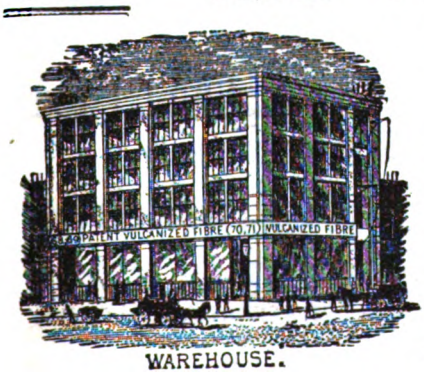
TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.—The directors propose a dividend of 15 per cent. (£1. 16s. per share) in addition to the 5 per cent. already paid, making 20 per cent for 1888, being the same as for 1887.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended February 1st, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,691.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The traffic receipts of this company for the month ended 31st January, 1889, amounted to £6,125.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The traffic receipts for the half-month ended January 31st, 1889, were £2,770, as compared with £3,279 in the corresponding period of 1888. The October receipts, estimated at £5,197, realised £5,325.

THE NON-CONDUCTOR OF ELECTRICITY.



WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

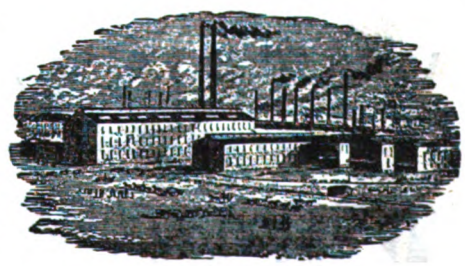
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 561.—Vol. XXII. FRIDAY, FEBRUARY 15, 1889. Price Fourpence.

NOTES.

The judgment in the appeal case of Edison-Swan *versus* Holland and Others (Anglo-American Brush Company) will be delivered on Monday morning next at 11 a.m.

The Friday evening lecture at the Royal Institution was last week delivered by Sir William Thomson, who chose for his subject "The Electrostatic Measurement of Potential." After describing the several instruments and methods with which electricians are already familiar, Sir William exhibited a new low-reading electrometer based upon the same principle as the electrostatic voltmeter which was first described before the Glasgow Philosophical Society, in April, 1887 (see *The Electrician* of April 29th, 1887, p. 542). The range of this instrument extended from 400 volts to 10,000 volts, whereas the instrument now exhibited had a range of from 40 to about 120 volts. These two instruments, in fact, belong to an entire series of electrometers upon which Sir William Thomson is now engaged, and which will measure by electrostatic force potentials of from 40 volts to 50,000 volts. The standardisation of these instruments up to 200 or 300 volts is made exceedingly easy, by aid of the centi-ampere balance, with a battery of any kind, capable of giving a fairly steady current of one-tenth of an ampere through the balance and a platinoid resistance in series with it. The accuracy of the electromagnetic standardisation, within the range of the direct application of this method, is quite within one-twentieth per cent. A method of multiplication by aid of condensers, which was explained, gives an accuracy quite within one-fifth per cent. for the measurement of E.M.F. up to 2,000 or 3,000 volts; and with not much less accuracy, by aid of an intermediary electrometer, up to 10,000 volts. Such a potential as 10,000 volts is convenient for measurement by an absolute electrostatic balance, which was fully explained by the lecturer and illustrated by a drawing, but hitherto he has not been able to make sure of the absolute accuracy of this electrostatic balance to closer than one-half per cent. The results of a great number of measurements made in the Physical Laboratory of the University of Glasgow during the last two months, give the required number, commonly called "v," within one-half per cent. of 300,000 kilometres per second. It is well known that the number of electrostatic units of potential force in the electromagnetic unit of potential is essentially a velocity. Experiments have proved it to be so nearly equal to the velocity of light, that, from all the direct observations hitherto made, we cannot tell, said Sir William, whether it is a little greater, or a little less, or absolutely equal to the velocity of light. The velocity of light is known to be within one-quarter per cent. of 300,000 kilometres per second. Results of previous observers for determining "v" had almost absolutely proved for "v" at least as close an agreement with the 300 million metres as this. Sir William expressed his obligations to his assistants and students in the Physical Laboratory of Glasgow University, Messrs. Meikle, Shields, Sutherland, and Carver, who worked with the greatest perseverance and accuracy in the laborious and often irksome observations by which he had attempted to determine "v" by the direct electrometer method as exactly as, or more exactly than, it has been determined by other observers and other methods.

We publish this week an abstract of a very elaborate Paper by Dr. A. Von Waltenhofen in the *Centralblatt*, on the measurements of the insulation resistance of the wiring of the new Court Theatre, Vienna. From the care and skill which was evidently exercised the results obtained should be of a trustworthy character, and as such they are of value in helping to determine a reasonable value for the insulation coefficient. Taking the simplest, and what is probably the most satisfactory expression, $R = k\,E/C$, where R is the insulation resistance and C the total current, the final results obtained would correspond to a value of k somewhat exceeding 20,000, and therefore actually higher than any figure which has yet been proposed. The test, moreover, was taken with all lamps and fittings in place. On the other hand, this high standard of perfection was only attained after a careful series of tests on each individual lead, followed by the elimination of all wires whose insulation resistance was less than 0·1 megohm whatever their length.

Referring to our remarks in the last issue on the advantages of testing for insulation resistance under an E.M.F. at least as high as that at which the installation will be worked, Prof. Jamieson raises the objection that such treatment has a tendency to "break down" an incipient fault. But surely this is an argument which tends altogether the other way; the very object of the test is to discover faults, incipient or otherwise. If it is preferred to allow a fault to develop under the action of the normal current, what is the use of the test? On the other hand, we can sympathise with the feelings of a contractor when the existence of a fault has been discovered which it may take days or weeks to localise. It is

Digitized by Google

just this difficulty of localisation which induces many people to doubt the utility of insulation tests. But if a test be made it would seem better to make it a real test, and not an empty ceremony.

RETURNING to the question of incipient faults on installation wires we should be glad to ascertain whether it is actually a fact that they can, as a rule, be "broken down" by the application of a high E.M.F. The conditions of an electric light conductor do not readily admit of comparison with those of a submarine cable. It was owing to some uncertainty on this point that we last week suggested that it might be advantageous to keep a moderately high potential on the wire for some time before making the test.

STILL another claimant to the honour of the discovery of the principle of constant-current regulation by means of steam pressure has appeared in the person of Mr. J. KIRKHAM, whose claims are put forth in a letter from Messrs. JOHN SMITH and Co., of Moscow, which will be found elsewhere in this issue. It would, therefore, appear that there have been at least four separate and independent discoverers of this principle. However, we take this opportunity of stating that from facts which have come to our knowledge since our last reference to the subject, we are satisfied that the earliest observation of the principle was that of Mr. EDMUNDS himself in 1878. Mr. BERNSTEIN was perhaps the first actually to employ the device in this country, but Mr. KIRKHAM seems to have forestalled him in Russia by some three years.

ONE or two recent shipping disasters which have occurred on the western and south-western coasts are again directing local attention to the subject of connecting all the Coastguard Stations with each other and with the outlying lightships by telegraph or telephone wires. The Lifeboat Stations were in these instances at fault as to the real locality of the distress signals, and the crews of the ships perished in consequence. Electrical coast communication, it is said, would have notified the exact positions, and these lives might have been saved. The *Western Morning News*, we are glad to notice, is taking this matter up warmly, and petitions are being prepared praying that the Board of Trade or the Post Office may be allowed to establish the much needed cordon of electrical communication, on grounds both of humanity and of national safety.

THE theory of hempen-covered submarine cables seems to be finding favour in America as well as in some quarters nearer home, its advocates apparently relying on the fact that iron as a protector is corroded by the action of the sea, whereas hemp is unaffected by it. There are, however, other means of effectually overcoming this difficulty. Nor is this the only action that has to be guarded against. There are various species of teredo which attack the cables, and some of these marine parasites have a special fancy for hemp. Cables have been recovered from depths of twelve hundred fathoms with all the hemp eaten away. Again, it is a mistake to suppose, as does the writer in the Halifax (N.S.) *Chronicle*, from whom we quote this week, that once at the bottom of the deep sea the cable rests in undisturbed security. As a matter of fact, many localities are known to be liable to great disturbance from strong currents, and probably there are many more that we know not of. At least one cable has been destroyed in that way, although submerged at a depth of five hundred fathoms. On the other hand, it must be conceded that the absence of the iron sheath should tend to facilitate higher speeds of working.

AN ingenious system of multiplex telegraphy has been worked out by Lieut. PATTEN. In the systems at present in vogue synchronism is obtained by devices which are primarily of a mechanical character. Lieut. PATTEN has made a new departure, availing himself of the property of synchronism possessed by an electric motor supplied with alternating currents.

IN a recent number of the *Telephone* Mr. A. R. BENNETT records the interesting fact that he has found that looped metallic circuits are more liable to suffer from lightning discharges than single wires earthed at both ends. This is evidently an illustration of the "surging" or "resonant" effects discovered by Dr. LODGE, and the observation affords one more illustration of the general correctness of the theoretical views to which he has been led.

EVEN in the case of a non-oscillatory discharge we are not clear that the question, "which way the lightning went?" has any definite meaning. Mr. BENNETT, however, seems to think that it can be answered, when a spark to an earth terminal occurs, by observing on which side the greater heat effect has taken place. This we do not understand.

MR. SYDNEY EVERSHED complains that two "globular lightning" stories in one number of *The Electrician* is more than he can conveniently digest, especially as he firmly believes them all. But if Mr. SYDNEY EVERSHED only knew how many such stories we do not insert he would be the first to appreciate our moderation. In proof thereof we may cite a remarkable experience which happened in the South of France last year to a German Doctor of Divinity. This story has never before appeared in print; it came to us some weeks ago at second hand only, and under circumstances which render it at least as convincing as Mr. EVERSHED'S own assertion that "once he almost saw a fireball himself."

A TERRIFIC storm was raging, the Doctor had flattened his nose against the window pane, and was endeavouring by the well-known cardiacal method to estimate the distance of the storm centre, which seemed perilously near. Suddenly he was startled by the apparition of a vivid but persistent light, together with an uncomfortable sensation of heat in the facial region. At the same moment he became conscious of the fact that, despite his sudden impulse to retreat, he was absolutely unable to withdraw his nose from the pane against which it was flattened. By this time his vision had adjusted itself to the existing degree of brilliancy, and what was his horror as the conviction gradually stole over him that a fireball had attached itself to the window

Digitized by Google

pane, and was indeed virtually hanging from the tip of his nose, with nothing but the dielectic between! In this appalling situation the Doctor remained, expecting every moment to be his last, for a space which seemed, he says, two hours, but which, on a calmer estimate, he has since reduced to two minutes. At length the electrostatic pressure on the tip of his nose commenced perceptibly to diminish, and he presently had the inexpressible satisfaction of seeing the "globular" glide slowly away; and almost immediately after it burst with a loud report, tearing up the ground over a space of several feet, quite in the orthodox manner. It is painful to reflect that so magnificent an opportunity for the extension of our knowledge has been thrown away on a Doctor of Divinity. Had Dr. LODGE or Dr. HERTZ been the victim, science would have been enriched by a monograph of the utmost interest and value.

WE are glad to be able to announce that the ELECTRICAL TRADES DIRECTORY AND HANDBOOK, which is compiled and published at this office, is now ready for the current year. It is the seventh year's issue of this useful volume, and it has now reached the respectable dimensions of six hundred pages, crowded with information either indispensable or extremely valuable to all persons engaged in the electrical and allied trades.

St. Martin's-in-the-Fields Vestry.—The consent of this Vestry was given last week to the House-to-House Company's Provisional Order.

Italian Cables.—The Minister of War has decided to have a cable laid from the Island of Maddalena to the mainland. The contract has been given to an Italian firm.

Royal Society.—An important Paper was read yesterday before the Royal Society by Dr. John Hopkinson, "On the Magnetisation of Iron at High Temperatures."

Portrait of Major-General Webber.—Our contemporary, the *Municipal Review*, published last week an excellent "ink-photo" portrait of Major-General Webber, C.B.

Exeter.—The Exeter Electric Light Company has purchased the "Rockfield Hat" block of buildings in New North-road, and machinery is to be erected at once for the supply of private houses in the city.

Barcelona.—The *Boletin Oficial* of the 7th inst. states that on the 19th inst., at 2 p.m., tenders will be accepted at the Central Telegraph Station of Barcelona for the establishment and working of a telephone system at Manresa.

Chelsea Vestry.—At a meeting of this Vestry last week permission was given to the Chelsea Electricity Supply Company to lay down an iron pipe to convey water from the Sloane-square railway station to their central station in Draycot-place.

An Electric "Star."—The paper-distributing carts of the *Star* are now illuminated by electricity. The light is a ten candle-power incandescent, run off an accumulator. The apparatus was provided by the United Electrical Engineering Company.

Important Sale of Electrical Apparatus.—It will be seen by our advertisement columns that Messrs. Wheatley Kirk, Price and Goulty have been instructed to sell at an early date the entire electrical apparatus belonging to the Electric "Sun" Lamp and Power Company, now in liquidation.

Strand District Board.—Applications from the Electrical Power Storage Company and from Messrs. Hill and Co., on behalf of Mr. Koerber, asking for the Board's support of their applications for Parliamentary powers, were read at a meeting last week, and referred to the Electric Lighting Committee.

Laxton's Price Book 1889.—The 1889 edition of this useful work, although some twenty pages smaller than that of last year, contains as usual an immense amount of valuable information. Eight pages of small type are this year devoted to electric lighting instead of less than six. There is, however, plenty of room for more detailed information under this heading.

"Some Curiosities of Magnetism."—Under the above title a most interesting address was delivered at the London Institution on Monday last by Mr. Shelford Bidwell, F.R.S. Although intended mainly for a popular audience, and couched in an eminently intelligible and "popular" vein, Mr. Bidwell's address and experiments could scarcely fail to have interested and instructed even a highly technical audience.

English Plant on the Continent.—In spite of the natural preference which is generally shown on the Continent for home-made machinery English plant often carries the day. As an instance of this we may mention that Mr. Albert Dawson, of Lille, has recently completed an electric light installation at the works of M. Léon Olivier at Roubaix, in which Kapp dynamos made by Messrs. W. H. Allen and Co. are used, as well as Cockburn cut-outs.

Electric Lighting in Liverpool.—The Watch Committee have had before them a letter with reference to the application of the Liverpool Electric Supply Company for the consent of the Corporation to apply for a Provisional Order, in which it was stated that the company are prepared to submit to a purchase clause, exercisable at the end of twenty-five years and at the end of every succeeding term of seven years. It was resolved that consideration of the matter be postponed for a month.

Institution of Electrical Engineers.—A students' meeting of the above Institution was held on Friday evening, February 8th, Mr. J. Rance, jun., Assoc. Inst. E.E., in the chair. A Paper was read by Mr. T. L. Horn on "Insulation Resistance and some of the Practical Difficulties in obtaining good Insulation on Electric Light Circuits." A discussion followed, in which Messrs. G. H. Nisbett and R. W. Paul took part, after which Mr. Rance made a few remarks, and a vote of thanks to him closed the proceedings.

The Snowstorm.—The snowstorm of the 10th inst has done very little damage to the telegraph and telephone lines in this country, owing, no doubt, to the fact that the flakes fell in a dry, powdery condition. On the Continent, however, the lines have been greatly interrupted, especially in France, Germany, and Belgium. In Germany, however, the breakdown caused little inconvenience, the underground system being now so complete that almost all the chief towns in the Empire maintained their telegraphic communication uninterrupted.

The Ward Electrical Omnibus.—This omnibus made two runs on Friday last. On the first trip it left the depôt and made a long run of about 7½ miles through the City and back. The second run was made through some of the busiest streets in London, right in the thick of the forenoon traffic. The omnibus left the depôt about 9:30, went up Regent-street and Portland-street on to the Marylebone-road, along Edgware-road to Westbourne-grove. The car then ran on to Paddington Station, back again down Edgware-road, Oxford-street, Grosvenor-square, coming down Regent-street through the ordinary thick daily traffic. The length of the second run was about 8 miles.

Multiplex Telephony on Long Lines.—Mr. D. S. Sinclair, engineer to the National Telephone Company, lately read a Paper on this subject before the Glasgow Philosophical Society. The lecturer described his Paper as a *résumé* of what had been done, and what was likely to be done, in regard to this subject. He showed that in no way could multiplex be done on single wires as such, but by employing return loop circuit wires three sets of telephones could be used on two such circuits. In America four sets of instruments on two circuits had been tried, but this the lecturer condemned, holding that that system destroyed the qualities of loop circuits, while using three sets retained them.

Exports of Telegraphic Wires and Apparatus connected therewith.—The year has opened with a very satisfactory improvement in our exports under this head. The following com-

Digitized by Google

parative figures of the exports last month are taken from the Board of Trade returns. We add the aggregate figures for the previous 12 months :—

	1886.	1887.	1888.
Year	£992,667	..... £817,385	..... £521,174
	1887.	1888.	1889.
January.....	£14,442	..... £41,231	..... £113,230

The shipments last month must evidently have included some large items of an exceptional character.

Drake and Gorham's Catalogue.—Messrs. Drake and Gorham have just issued a new edition of their illustrated catalogue and price list. This publication is very complete, and contains quotations for the principal apparatus likely to be required by anyone contemplating an installation of accumulators. Amongst other things we notice Messrs. Drake and Gorham's "disc" ammeter, which seems a cheap and simple instrument, and a very useful table, which gives at a glance the type and number of cells required for a given number of lamps, with total price of the same. Messrs. Drake and Gorham have also issued some new working instructions, which furnish all sorts of practical hints in a small space, and which must prove of great assistance to those in charge of accumulators.

Absolute Resistance of Mercury.—In a recent number of *Wiedemann's Annalen* F. Kohlrausch publishes an account of a redetermination which he has carried out with elaborate precautions of the absolute resistance of mercury. The method employed was Weber's method of damping, with some slight modifications due to Dorn. The result arrived at is that the resistance of a cubic centimetre of mercury at 0°C. is 94,060 centimetre seconds. In order to compare this determination with the B A. unit, Mr. Glazebrook has compared one of the author's mercury standards with the B.A. unit in the Cavendish Laboratory, and finds that according to Kohlrausch's determination one B.A. unit = 0·9866 ohm. This would give a length of between 106·2 and 106·3 for the column of mercury one square centimetre in section having a resistance of one ohm.

Society of Arts Motor Competition.—The Council of the Society of Arts, on the award of the judges, Prof. A. B. W. Kennedy, F.R.S., Dr. John Hopkinson, F.R.S., and Mr. Beauchamp Tower, have awarded a Society of Arts gold medal to each of the following competitors :—Class A.—Motors in which the working agent is also produced—Davey, Paxman and Co., Colchester, eight horse-power compound portable engine. Class B.—Motors to which the working agent must be applied : 1st. Motors under ten horse-power (actual)—British Gas Engine and Engineering Company, Albion Works, Gospel Oak, six horse-power nominal Atkinson's "Cycle" gas engine ; 2nd, motors over ten horse-power (actual)—Crossley Brothers (Limited), Manchester, nine horse-power nominal "Otto" gas engine ; 3rd, Dick, Kerr and Co, Leadenhall-street, E.C, eight horse-power "Griffin" gas engine.

Barnet.—At the last meeting of the Barnet Local Board the clerk reported that, in accordance with the instructions of the Board, he had written to Messrs. Joel, inquiring the cause of a recent failure of the electric lamps. With reference to the actual cessation of light, Messrs. Joel replied that they were reluctantly compelled to attribute the failure to the breaking of the circuit through wilful mischief. They had endeavoured to ascribe previous difficulties to accident ; but could no longer refrain from saying wilful mischief was the cause, the wire at one of the lamps being severed and twisted up over the lamp. No discussion took place on the letter, as the whole question will be considered on the receipt of a report on the electric lighting of the district from the expert engaged by the Board. On the 6th inst. there was another breakdown of the electric light, and the town was in darkness for three hours. This is the fifth total failure in five months.

The Progress of the Telegraph and the Telephone.—The *Journal Télégraphique* contains some interesting figures relating to the progress of telegraphy and telephony during the past year. Since 1887 the number of telegraph offices, including those in the United States, has increased by 7,200 ; and during the year Germany opened her 10,000th office. Telephony has also made considerable progress. In the United States there are at present 750 systems and 200,000 subscribers. In Europe Germany leads the way with 167 systems and 26,000 subscribers ; England comes next with 125 systems and 20,000 subscribers ; then follow Sweden, with 150 systems and 15,000 subscribers ; France with 39 systems and 10,800 subscribers ; Italy, with 49 systems and 9,600 subscribers ; Switzerland, with 71 systems and 8,000 subscribers ; Russia, with 36 systems and 7,600 subscribers. In March, 1888, Germany possessed 148 inter-urban trunk lines, while in Belgium and Switzerland all towns with exchanges are in telephonic connection with one another.

Incandescent Lamps for Army Signalling.—Some important signalling experiments were carried out at Aldershot last week in the presence of Lieutenant-General Sir Evelyn Wood and Colonel F. C. Keyser, C.B., inspector of army signalling for the United Kingdom. The main object was to test a new signalling electric hand lamp made by Messrs. J. P. Rees and Co. The flashes are caused by the making and breaking of contact between the battery and the lamp, and they are for all practical purposes instantaneous. The lamp will burn from ten to twelve hours without having to recharge the battery. The night was far from being a satisfactory one for long distance signalling, being hazy and showery at intervals. Mr. Rees and party took up a position on Foxhills, near the Great Flash, a distance of about three miles. At this distance, except during clear intervals, the oil lamp could not be seen, or was only just discernible with the field glasses, whereas the electric lamp shone out clearly, and messages were transmitted with the greatest ease.

New Mexican Cable.—In our issue of 8th February we stated that a second cable was to be laid between Vera Cruz and Galveston. Later advices from Mexico bring some particulars of the undertaking, from which we learn that the new cable is to be used for the South American traffic, the present cable between Vera Cruz and Galveston being used exclusively for Mexican business. The Mexican Telegraph Company has arranged to lay the new cable in conjunction with the South American Telegraph Company, which has a line across the Isthmus of Tehuantepec. The increase in the South American business has become so extensive of late as to make it impossible to handle both that traffic and the Mexican business upon the present Mexican cable. The new cable will be laid from Coatzacoalcos, about 200 miles south of Vera Cruz, to Galveston, a distance of about a thousand miles. Advices from Mexico dated January 24th, announce the arrival of the steamer "Faraday" with the new cable, which is said to weigh about three tons to the mile.

Tenth Annual Exhibition of Meteorological Instruments.—The following circular has been issued by the Royal Meteorological Society :—"The Council of the Royal Meteorological Society have arranged to hold, at 25, Great George-street, Westminster (by permission of the Council of the Institution of Civil Engineers), on March 19th to 22nd next, an exhibition of *instruments connected with atmospheric physics* invented during the last ten years, especially those used for actinic and solar radiation observations. I am therefore instructed by the Exhibition Committee to invite your co-operation, as they are anxious to obtain as large a collection as possible of such instruments, &c. The committee will also be glad to show any *new* meteorological instruments or apparatus invented or first constructed since last March, as well as photographs and drawings possessing meteorological interest. Should you be willing to co-operate in the proposed exhibition I should be obliged by your furnishing me (*not later* than March 1st) with a list of the articles you will be able to contribute and an estimate of the space they will require.—(Signed) WILLIAM MARRIOTT, Assistant Secretary."

Halifax.—At the quarterly meeting of the Halifax Town Council last week several communications respecting electric lighting were read. Mr. Holroyd Smith wrote to the effect that if he received the support of the Corporation he would apply for Parliamentary powers and start a central station immediately. He further suggested that the Corporation should agree to take, say, 1,000 incandescents and 25 2,000 candle-power arcs to light the public buildings and main streets with.

Digitized by Google

A subsequent letter was received from Mr. Holroyd Smith suggesting that in lieu of spending £30,000 on gasworks' extension, a scheme might be arranged for meeting the increased demand by electricity. On February 5th the Anglo-American Brush Corporation wrote to say that they had seen Mr. Smith's second letter, and they concurred with its contents. Messrs. Foster and England, solicitors, also wrote, presenting a memorial signed by several large tradesmen in the centre of the town, requesting the consent of the Corporation to their arrangements with the Schmidt-Douglas Company of Bradford, for the erection of a central lighting station. A letter from Messrs. Blakey, Emmott, and Co., was also read, asking for permission to run cables above and below ground from their proposed central station. A Mr. J. R. Smith wrote on the same subject, calling attention to his own views of electric lighting, which were submitted to the Corporation years ago, and offering his advice gratis in the event of the Corporation deciding to introduce the light into Halifax. All these communications were referred to a special committee.

The Telephone in Austria.—The Secretary of the Telephone Company of Austria sends us the following interesting extract from a letter recently received from their manager in Austria, Mr. R. H. Krause :—"In Czernowitz we have had a constant fight with the ice this winter. Ever since the New Year heavy damp fogs have come up the Pruth Valley, in Czernowitz the thermometer standing at 12·15° Reaumur. The result was that pure crystal ice up to and over half an inch in thickness was formed on the wires. We have so far succeeded in preserving the lines, never more than ten broken, which were at once repaired by the permanent staff in spite of the cold. Of course the heavy weight on the wires made many contacts, but we have managed up till now to keep matters going. In Graz we once had great danger from snow. The soft damp snow so dangerous to lines began falling at night. Here our instructions again worked well. Two town night watchmen receive annually a small sum and have the duty of informing our superintendent of storms of this specially dangerous snow. Thus within half an hour our men were out at all the dangerous spans knocking off the snow, and we succeeded in getting through that night and the next day with but one wire broken, and with an extra cost of about 10s. only for hot drinks for the men." The number of telegrams which passed through the hands of the company during 1888 in connection with the Austrian Government telegraph service was 110,843.

Anglo-German Telegraphs.—Herr von Stephan, Postmaster-General of the German Empire, stated in the Reichstag on Friday last that he had a gratifying communication to make with respect to the telegraphic intercourse between England and Germany. Hitherto there had been no direct connection between the telegraph systems of the two States, owing to the fact of the submarine cables being in the hands of private companies. But the concessions of these companies having lately expired, the two Governments took over the respective cables, with all their local belongings, and at the same time negotiations were entered into with Belgium and Holland, so that from the 1st of April next direct communication between Germany and England would be available by means of fourteen, instead of, as hitherto, only eight, lines, while at the same time the tariff for transmission would be considerably reduced. Hitherto, for example, the tariff to England had been a little more than 2d. per word, with an initial charge of 4d., but this latter was now to be abolished altogether, while the word-tariff would be reduced from 2d. to 1½d. Thus, for instance, a telegram of 12 words to England, which now costs a little more than 2s. 8d., would in future be sent for about 1s. 8d., implying a saving of 1s. on so short a message. "This gratifying result," said the Minister in conclusion, "we owe to the hearty co-operation of the English Government with that of Germany, and to the energy and intelligence of the higher telegraph officials in London and Berlin." We learn in this connection that Mr. J. C. Lamb, accompanied by Mr. H. C. Fischer, has just returned from the Continent having completed the necessary arrangements with the German, Dutch, and Belgian Governments, the final arrangements with France being still the subject of negotiation.

The Effect on Electric Lighting in the United States of the Bate Decision.—The opinion of the Supreme Court in the case of the Bate Refrigerating Co. *v.* Hammond and Co. is stated, says the *Electrical World*, to affect favourably, as regards prosecution of infringements, the following Edison electric light patents, upon which suits have been pending for some time against competing electric light companies, and the prosecution of which suits has been delayed up to the present time by the technical obstacle which the decision of the Supreme Court removes. Those patents are :—

No. 223,898, covering the broad invention of the filament lamp.
No. 227,229, covering the use of high-resistance enclosed conductor in a vacuum chamber entirely of glass.
No. 265.777, covering the perfection of the carbon filament in the driving out of the occluded gases in the vacuum by the heat of the current.
No. 265,311, covering broadly the employment of a lamp removable from the socket.
No. 251,554, on positive connection between the lamp and the socket, so that the position of the lamp can be reversed.
No. 230,255, on making the closed chamber of the lamp in two parts, fused together.
No. 266,447, on making the closed chamber of the lamp in two parts, fused together when the globe is made from pot blown glass.
No. 248,419 and No. 264,698, on details of glass construction.
No. 248,424, on providing a pendant incandescent lamp, removable from its socket, with a shade or reflector placed above it, so that the lamp can be moved and placed without disturbing the shade.
No. 263,140, covering the use of two or more commutator brushes.
No. 251,540, on making the filament of bamboo or other fibrous material, having the fibres running parallel throughout the length of the filament.

Suits on these patents are pending in the Circuit Court of the Southern District of New York against the United States Electric Lighting Company, the United States Illuminating Company, the Consolidated Electric Light Company, and the Swan Incandescent Electric Light Company. In addition to the above patents, the Edison feeder patent, No. 264,642, on which suit was brought *v.* Westinghouse, Church, Kerr, and Co., at Trenton, N.J., is also held to be affected favourably by the decision of the Supreme Court.

The Continental Cables.—The following statement has been circulated by the *Central News* :—"The English and French Governments have failed to arrive at an agreement respecting the purchase of the Anglo-French cables from the Submarine Telegraph Company. At the time when the British Government decided definitely not to renew the concession to the Submarine Telegraph Company it was understood that the two Governments should purchase the cables of that company at a valuation, and it is alleged that a promise was given by the British Treasury to that effect. The French Government, however, is now objecting to the purchase of these cables on any terms, on the ground that they are too old for satisfactory working, and that it would be preferable to lay new and better cables. Mr. W. L. Jackson, M.P., of the Treasury, and Mr. Patey of the General Post Office, went to Paris recently, and had prolonged conferences with M. Coulon, Minister of Posts and Telegraphs, on the subject, but without altering the opinion entertained by that gentleman. Since these conferences in Paris M. Coulon has sent engineers from France to inspect and test the submarine plant and cables, in conjunction with the English Post Office engineers. A thorough examination was made at Dover, as well as at East Dean, near Eastbourne, and as a result of these investigations, the *Central News* learns, reports have been forwarded to Paris which are by no means favourable to the purchase of the submarine cables. It is believed that the British Government will yield to the wishes of France in this matter, and that entirely new cables will be constructed for working between the two countries. It is somewhat significant, too, that although an agreement had been signed by Belgium and England for working the Anglo-Belgium cables, these have not yet been bought, nor has the British Treasury made any offer for them. It is probable that if new cables are laid between England and France, they will also be laid between England and Belgium. This new development of affairs is a hardship upon the Submarine Company, but it is difficult to see how, in face of the determined opposition of France, the cables of that company can be purchased by England."

THE ELECTROLYTIC SEPARATION AND REFINING OF METALS.*

HISTORICAL SKETCH.

BY DR. G. GORE, F.R.S.

More than thirteen hundred years ago Zosimus mentioned the earliest known fact respecting the electrolytic separation of metals, viz., that by immersing a piece of iron in a cupreous solution it acquired a coating of copper. Ever since that time the same fact has been commonly observed by workers in copper mines, that their tools of iron or steel became coated with a film of copper by contact with the water percolating through the mines; the water holding in solution blue vitriol derived from oxidation of mineral sulphides of copper contained in the rocks. Paracelsus in the years 1493 to 1541, and even Stisser, the professor of chemistry in Helmstadt, as late as 1690, believed that by this process the iron was changed into copper.

The discovery of chemical electricity by Volta and the invention of the voltaic battery as an instrument for producing it did not occur until about the year 1799. Wollaston soon afterwards observed that "if a piece of silver in connection with a more positive metal be put into a solution of copper, the silver is coated over with copper, which coating will stand the operation of burnishing" (*Philosophical Transactions* of the Royal Society, 1801). About the same time Mr. Cruickshank passed an electric current from his voltaic battery through a solution of sulphate of copper, and found that the copper attached itself to the wire connected with the zinc end of the battery, and stated that the metal was "revived completely" (Wilkinson's "Elements of Galvanism," Vol. II., 1804, p. 54). In 1805 Brugnatelli also observed that when the current entered the liquid by means of a piece of copper, the copper was dissolved and then deposited upon the negative pole ("Annals of Chemistry").

In 1831 Faraday discovered magneto-electricity, or the production of electric currents by means of mechanical power acting through the medium of magnets, a discovery which enabled all the subsequent inventions and improvements in dynamo-electric machines to be made, and the refining of metals by electrolysis to become commercially possible on a large scale. When he made this discovery the electric current he obtained was so very feeble that he was barely able to detect it, and he remarked: "I have rather, however, been desirous of discovering new facts and new relations dependent on magneto-electric induction than of exalting the force of those already obtained, being assured that the latter would find their full development hereafter" ("Experimental Researches," para. 158). This prediction has since been abundantly verified.

In 1836 De la Rue observed that the copper deposited by the voltaic current in a Daniell's battery cell gradually became thicker, and might be stripped off in the form of a separate sheet of metal from the surface upon which it had been deposited. About the year 1839 Jacobi, of St. Petersburg, and soon afterwards Jordan, Spencer, and others, made and published their experiments on electrotyping in copper, and thus made the process of depositing that metal familiar to the public.

From that time until the present, copper has been constantly deposited on a commercial scale as a coating upon various articles of iron, &c., in order to protect them; the electrolytic process has also gradually extended and been employed to form ornaments and other articles, until at length copper of more than one inch in thickness has been deposited, and copper statues weighing several tons have been formed by the process. Electro-deposited copper has also been frequently analysed and found to be extremely pure—so much so, that it has been employed in the Royal Mint to alloy with gold in making the standard coins of this realm. Its deposition on a large scale and great degree of purity, thus foreshadowed the electrolytic refining process.

The first actual commercial application of electrolysis to the refining of copper is to be found in a patent (No. 2,838) granted to James B. Elkington (son of the late G. R. Elkington, the original patentee of commercial electro-silvering and gilding) Nov. 3rd, 1865, entitled "Manufacture of Copper from Copper Ore." In this process plates of crude copper are used as anodes suspended in "troughs charged with a nearly saturated solution of sulphate of copper," the cathodes or negative plates being formed "of pure copper, rolled very thin." As the crude copper dissolves, pure copper is deposited upon the negative sheets. The patentee proposed to use a series of depositing troughs, each containing a set of properly connected anodes and cathodes, the electrolysis being effected by a current obtained from a magneto-electric machine. The insoluble residue which falls from the anodes to the bottom of the liquid frequently contains "silver, some gold, and also tin and antimony."

In a second patent (No. 3,120), taken out by the same patentee, Oct. 27th, 1869, for the "manufacture of copper, and separating other metals therefrom," impure copper, and especially that which contains much silver, is cast with a "T-shaped head of wrought copper," to enable it to be conveniently suspended as a dissolving plate in the depositing vessel.

"These plates are placed in fireclay jars, ranged longitudinally in troughs on a slightly-inclined, pitched, and otherwise prepared wooden floor, in the dissolving-house. Each jar has a hole in the bottom, closed by a wooden plug, and two holes in the sides, one low down and the other on the opposite side near the top, each jar being connected with the next lower one by a pipe or tube passing from the higher hole of the one to the lower hole of the other jar. The liquid current thus established between the solutions effects mixture of the layers of different density, maintaining all the liquids in the series of jars practically alike at top and bottom, notwithstanding the disturbing influence of the electro-deposition, which constantly tends to produce inequalities of density.

"The solution made use of is water saturated with sulphate of copper, a store of which is kept in a tank at the upper part of the depositing-room, whence it is admitted into the uppermost jars, and runs from jar to jar till all are filled. A solution may also be used obtained by boiling the deposit formed in the culvert or long flue by which the smoke from the copper furnaces is led to the high chimney.

"The tubes connecting the jars have clips attached to their india-rubber portions, acting as stop-cocks. When needful the clips are removed, so as to cause the solutions to mix, the dense layer from the bottom of one jar displacing the lighter portion from the top of another, until the density throughout becomes equalised. The outflow is received in a tank at the lower end of the room, from which it is pumped back to the upper reservoir. The plugged holes at the bottom of the jars enable the latter to be emptied on to the inclined floor, the liquid then flowing into the lower tank. The T-shaped heads attached to the plates enable them to be suspended in the jar, from horizontal copper bars having forks upon them. Interposed between the copper plates to be dissolved are suitably-suspended receiving plates for the deposit of the electrolytic copper. The receiving plates of one jar are connected by a conducting strip of copper with the cast plates of the next jar, and so on throughout. The series being coupled up into a circuit, the terminals are connected with one or more magneto-electric machines. The silver originally contained in the copper of the plates set for solution separates as a sediment, and ultimately accumulates as a deposit in the tank below, after the repeated workings and emptyings of the jars.

"Ores rich in silver are preferred as the source of cast copper for this treatment, since the silver is obtained as a bye product, without increasing the cost of obtaining pure copper from the impure metal."

These two patents of Mr. James Elkington contain the essential parts of the process of purifying copper by means of electrolysis, viz., employing slabs or thick plates of the crude metal as anodes; a series of depositing vessels with the solution flowing slowly through the whole of them, in order to keep it uniform in composition; the use of electric currents generated by means of mechanical energy, and the collection of the valuable impurities in the form of a sediment at the bottom of the vessels. The only other essential circumstance remaining is that of the occasional purification of the electrolyte by evapo-

* Extracted by permission of the Author from a forthcoming work on this subject. This book will be published at the Office of *The Electrician*.

Digitized by Google

rating it, and crystallising out of it the sulphate of iron and other soluble salts which gradually accumulate.

This process was developed and carried out on a large scale at Pembrey, near Swansea. The works at Pembrey formerly belonged to Messrs. Elkington, Mason and Co., but have since passed into the possession of the Elliott Metal Company (Limited), Selly Oak, near Birmingham, and at the present time this refinery is one of the largest and most perfect existing.

Meanwhile, *i.e.*, during the gradual extension of electro-deposition of copper, the originally minute, but, nevertheless, extremely important fact and phenomenon, of the production of an electric current by mechanical energy acting through the medium of magnetism, was developing slowly. This phenomenon when first discovered by Faraday in 1831 was so small as scarcely to be perceptible, and was first observed by him as "a sudden and very slight effect at the galvanometer" (Faraday's "Experimental Researches," Vol. I., p. 3). No sooner had Faraday published this seemingly unimportant effect than various experimentalists endeavoured to obtain it upon a larger scale. Prof. Forbes, of Edinburgh, Nobili, Ritchie, and others, as well as Faraday himself, quickly succeeded in obtaining electric sparks by means of the magneto-electric current. In 1832 H. Pixii invented and exhibited at Paris the first magneto-electric machine, and decomposed water by means of the current from it; this was followed in 1833 by Saxton's improved machine, and by that of Clarke in 1836; and on August 1st, 1842, was granted to J. S. Woolrich the first patent, No. 9,431, for a magneto-electric machine for commercial purposes. Woolrich's machine was for a long time used by Messrs. Prime, of Birmingham, for electro-silverplating.

Since that time the improvements in producing magneto-electricity have been numerous. In 1857 Werner Siemens invented his shuttle-wound armature; in 1860 Pacinotti developed his ring armature machine for yielding a continuous current, which formed the basis of Gramme's and other direct-current machines. In 1866 H. Wilde further increased the power of the apparatus by using a soft iron electro-magnet instead of an ordinary steel one to produce the currents; in 1867 Siemens, Wheatstone and Ladd each separately observed the fact of self-excitation by mechanical power, and developed the self-exciting machine; and in 1871 M. Gramme produced the first practical continuous-current machine for commercial purposes. Alterations and improvements have since that time succeeded each other so rapidly that there exists now quite a large variety of machines for converting mechanical energy into electric current. The magnitude, weight, and speed of the machines have also increased, until there are some which require several hundred horse-power to drive them; others which weigh as much as forty-five tons each, and some with armatures revolving at a speed of nine thousand revolutions a minute. The efficiency of the machine has also been increased until as much as 96 per cent. of mechanical energy imparted to the armature is converted into electric power. With a single dynamo now as much as thirty tons of copper are deposited per week. Even now the limit has not been attained, or even conceived, to the magnitude and uses of the machine, and dynamos will probably yet be constructed equal in amount of energy to the largest steam engines, and their power be applied to a great variety of purposes, mechanical, thermal, and chemical.

At the present time the process of electrolytic separation and refining of metals is extending rapidly; it is carried on at Pembrey, Widnes, Swansea, Tyldesley (Lancashire), Milton (near Stoke-upon-Trent), Paris, Marseilles, St. Denis, Angoulême, Biache (Pas de Calais), Hamburg, Stolberg, Berlin, Moabit (near Berlin), Oker (in the Hartz), Eisleben, Burbach (near Siegen), Frankfort-on-the-Maine, Schaffhausen, Stattbergerhütte (near Cologne), the Koenigshütte (in Silesia), Witkowitz (in Moravia), Stephanshütte (in Upper Hungary), Brixlegg (in the Tyrol), Ponte St. Martino (in Piedmont), Casarza (near Genoa), Pittsburg (Pennsylvania), Milwaukee (Wisconsin), Bridgeport (Connecticut), Omaha (Nebraska), Ansonia (Connecticut), St. Louis (Missouri), Newark (New Jersey), Cleveland (Ohio), Longport (near New York), Santiago (Chili), Chihuahua (Mexico), &c. At Messrs. Balbach's Works, Newark (New Jersey), sixty tons of copper are deposited and refined per week. "Messrs. Bolton, at Widnes, and Messrs. Vivian, as well as Messrs. Lambert, at Swansea, are each depositing from forty to fifty tons per week, by currents from 5,000 to 10,000 amperes" (*Nature*, January 26th, 1888, p. 303). The "daily quantity refined at Oker is two and a-half tons; and the total amount in Germany and Austria is about six tons daily." Messrs. Elliott and Co., of Pembrey (near Swansea), deposit nearly the largest amount, forty-five to sixty tons per week, in this country. I am informed from a direct source that the Bridgeport Copper Company, of Bridgeport (Connecticut), electrolytically refine "one million pounds of copper per month," or about 108 tons per week, "by means of three dynamos."

REVIEWS.

Practical Electrical Measurements. By J. SWINBURNE. (London: Alabaster, Gatehouse and Co.)

This very interesting and useful book is mainly a reprint of a series of articles published in our contemporary, the *Electrical Review*. It deals with instruments and methods used principally in connection with heavy electrical engineering, and there is no doubt plenty of room for it, as, although the standard book of Kempe on electrical testing and other later works, notably, Ayrton's excellent "Practical Electricity," supply the wants of telegraph engineers and workers in laboratories, there has hitherto been no book exclusively devoted to the more ponderous branch of electrical measurement in the workshop and the dynamo room. Probably no better writer than Mr. Swinburne could have been chosen, for he combines in an uncommon degree practical experience and theoretical knowledge of almost every department of this subject. Anyone who knows Mr. Swinburne will be aware that he cannot be dull, and, as was to be expected, we find here and there in this book passages which will raise a smile, serious and solid as are the subject and its general treatment. One or two instances may be quoted. Thus, ". . . an installing engineer who would not scruple to dispense with a voltmeter and judge the electromotive force by the look of the lamps, searches for ground contacts with a forty-guinea bridge in conjunction with one defective Leclanché cell, and a pivoted detector which sticks." This type of electrician is, however, almost extinct; but unhappily the one referred to in the following explanatory paragraph still flourishes—the passage is taken from the preface:—"The writer has avoided using mathematical symbols, partly to make the book more readable, and partly with the hope of setting an example to others. The pedantic fashion of dragging mathematical symbols into all electrical literature, and the respect commanded by an analytical investigation, even on false data, often lead writers to mar work otherwise good, by getting out of their mathematical depths and writing nonsense to look learned."

The book is divided into 12 chapters, dealing with resistance, voltmeters and ammeters, their winding and calibration, wattmeters, recording meters, the testing of dynamos, motors, batteries, arc and incandescent lamps, mirrors, and lastly alternating currents. It is not too much to say that in the whole book there is not a paragraph that is not the result of careful and independent thought, and although one is sometimes disinclined to accept the author's conclusions, he is always suggestive and helpful. The first chapter, on resistance, contains an account of several useful methods of measuring very low resistances, such as low-tension armatures. Probably the best of these is a modification by the author of an arrangement by Heaviside or Kirchhoff, the galvanometer being differential; but the writer is inclined to agree with the author that in practice it is convenient to pass a fairly large current through the resistance to be measured, taking the volts and amperes. The new low-reading voltmeter of Ayrton and Perry should be found useful for such work, or a still newer instrument which Captain Cardew recently showed the writer. Perhaps one of the small instruments sold for testing secondary cells would answer the purpose. A hint may be given by the writer while on this subject. It is a very difficult matter to be sure of all the joint

Digitized by Google

in an armature, but bad or indifferent joints may generally be discovered in low-tension machines by sending a current through the armature, and taking the fall of potential from sector to sector by means of any suitable sensitive galvanometer. Any irregularity is thus easily detected. Several special portable instruments for measuring resistances are described, suitable for rough work, but the "Universal" galvanometer of Siemens, which is perhaps the most sensitive of the portable instruments, is not referred to.

The only workers at that much-talked-of-but-little-used instrument, the ohmmeter, appear to have been Ayrton and Perry, Evershed and the author, to the first two of whom the idea of the instrument and the first example are due. Evershed has recently overcome, by an ingenious arrangement of the winding, what was a source of error in the principle of the ohmmeter as originally introduced, viz., that if it is joined up as a "short shunt" the shunt current goes through the series; while, if used as a "long shunt," the shunt is affected by the fall of potential due to the resistance of the series coil. A very good method of compensating for this error was first used by the author in a wattmeter, and is explained under that head.

On the subject of range and proportionality it is very properly pointed out that in instruments for special cases, such as for ordinary electric lighting work, the scale should be very open just where readings are wanted. This is a matter that makers would do well to attend to. Thus, for ordinary 100-volt installations voltmeters are not wanted to read less than 90 volts (except, perhaps, on the Grosvenor Gallery circuits), or more than 110, and the scale should be made as open as possible over that range. The author thinks—and gives his reason for thinking—that when an instrument has its scale marked off into equal divisions it must be regarded with suspicion.

Under voltmeters and ammeters the principles involved in the various types are discussed, and descriptions and illustrations of a large number are given. The excellent instrument of Raworth, made by Siemens Bros., which is supplanting the Siemens dynamometer for direct-current work, is not mentioned; probably it was scarcely known when the article was written.

In voltmeters for alternating currents there has hitherto been only that of Cardew, as electrometers have not come into practical use for high E.M.F.s, and have not been available for low E.M.F.s. There is likely to be a great improvement in this direction, as the new multi-cell electrometer of Sir Wm. Thomson, described by him last week at the Royal Institution, promises to be a most useful instrument, both for direct and alternate currents. For the latter it will be very useful. The Cardew voltmeter, though a most ingenious and valuable instrument, has the disadvantage of taking a good deal of power. The author states that the instrument to read to 120 volts takes 40 watts at that E.M.F. This is a very serious consideration, and in continuous use would cost the consumer on an ordinary central station system £8 to £10 per annum for power, as it would take nearly one (old) Board of Trade unit per day. The 120-volt instruments take rather less than 30 watts at 100 volts. This is not so much as that cited by the author, and there is little doubt that it will be found possible to make the instrument much more economical of power.

Recording meters have a chapter to themselves. The electrolytic meter, so largely used in the United States, is adversely criticised. The general opinion in this country is, with the author, opposed to their use on parallel systems, principally on account of the loss in the resistance used in the lamp circuit in connection with them and the variations of light resulting therefrom. But this cannot be as serious as is supposed, or the principle would not have been so extensively applied. On this point the recent Paper by Mr. Jenks is silent.

Faure's meter is described. It was the first of the Faraday disc or, rather, Barlow wheel meters, and, if we recollect rightly, it was in Faure's specification that the statement was first made that the torque varied as the square of the current and the friction as the square of the speed, so that the speed was as the current. This sounds so satisfactory that it has been generally accepted in connection with all meters having vanes, but we now know it to be incorrect. Probably no one but Mr. Ferranti knows how much labour is necessary to make a meter of this type practical. Ayrton and Perry's clock meter is described, and Aron's modification thereof, and a good figure is given of Forbes' ingenious windmill meter.

Of recording meters for alternate currents little or nothing is said; they scarcely existed when the book was written.

The long and instructive chapters on the calibration of voltmeters and ammeters must be passed over.

A good deal of useful information is given on the testing of dynamos and motors, but the writer must object to the author's remarks on what he considers the harmful custom of making slow-speed dynamos. Much that he says is right, but it is not right to take the output of a dynamo as directly proportional to speed, and internal losses as constant. As a matter of fact, the output of a dynamo does not (or should not be allowed to) go up as the speed, and the losses are not constant at all speeds, as the author assumes. The last chapter is on "Alternating Currents," and it will repay careful study. A strong protest is made against the custom of considering, for convenience of mathematical treatment, that all dynamos give sine curves, or that even if they are not so obliging, that there are properties in a system of converters which reduce the curve to a sine curve. While agreeing that the curve of a machine depends upon what is going on in the external circuit, an objection must be made to the following passage:—"If the dynamo is feeding 100 transformers, each at half load with the iron not saturated, the curve will not be the same as when it feeds 50 fully-loaded transformers with cores highly saturated at each extreme." As a matter of fact it is not usual for transformers to be designed with such conditions as regards their saturation. In his recommendations in connection with alternate-current measurements considerable use is made of an imaginary wattmeter without self or mutual induction. If such an instrument existed it would undoubtedly be very useful, but as it is not at present available its use on paper is only of advantage in considering what it is we want to measure. This is a consideration that is of the very first importance, and the author lays stress upon the use of the wattmeter probably as affording the simplest means of explaining the subject, and his explanations are very clear. Altogether the book is an excellent one, the few points that have been objected to in this notice being almost the only ones that out of a large mass of matter have struck us as perhaps open to criticism.

"The Electrician" Electrical Trades Directory and Handbook for 1889 (*The Electrician* Printing and Publishing Company (Limited), 1, Salisbury Court, Fleet-street, E.C. Price 3s. 6d., postage extra.)

This exceedingly comprehensive and useful Directory, which is issued from the press of *The Electrician*, has this year taken up a foremost place among trade handbooks of this kind. The Directory sections have been greatly enlarged and more carefully classified, and further additions made to the Biographical section. Numerous tables have been incorporated bearing upon subjects of importance to all branches of electrical trade; besides many new features of more general commercial interest.

REPORT ON THE INSULATION MEASUREMENTS MADE ON THE ELECTRIC LIGHTING INSTALLATION IN THE NEW COURT THEATRE, VIENNA.*

BY DR. A. VON WALTENHOFEN.

During the building of the new Court Theatre at Vienna I received instructions to thoroughly test the insulation of the various leads and cables while the installation work was still in hand. One of the chief reasons for this work was the idea that the building being constructed to so great an extent of iron would be very prejudicial to so extensive a system of wiring as exists in this theatre. Another reason, however, was that the newspaper reports which appeared when the much-to-be-regretted breakdown occurred in the opera lighting (although this breakdown was entirely due to the faulty boilers, and was in no way whatever attributable to any electrical causes) led to a report being circulated to the effect that the cables and leads in the opera house were defective, and fears were entertained that similar defects might appear in the installation in the new Court Theatre, which was already in progress.

* Abstracted from the *Centralblatt für Electrotechnik* by R. H. Krause.

Digitized by Google

Under these circumstances it was considered advisable to test this installation in a systematic and thorough manner, so that a reliable and unprejudiced opinion might be obtained as to its efficiency, and that any faults might be at once discovered and rectified.

Before referring to the measurements themselves, I will give a short description of the installation, the details of which have been kindly communicated to me by Mr. T. W. W. Melhuish, Assoc.M.Inst.C.E., the chief engineer of the Electrical Department of the Imperial Continental Gas Association.

The central station which the I. C. G. A. has erected is situated only a short distance from the Hofburg Theatre in the Shenkenstrasse, No. 10. In it are eight boilers (Babcock and Wilcox) which supply steam to eight combined steam dynamos, five of these being of 130 and three of 170 horse-power, the former yielding 130 amperes × 540 volts, and the latter 250 amperes × 400 volts. The different voltage of the machines is due to the different arrangements of batteries in the two theatres, four being placed in series in the Opera House, while in the Burg Theatre only three are used in series; this will, however, soon be altered.

The central station is connected by means of underground cables with both theatres, and in the cellars of these are placed the accumulators, in each over 100 tons of plates, so that this is the largest installation of the kind in existence.

In the Hofburg Theatre the accumulators in use were manufactured at Baumgarten, near Vienna, in the factory of Messrs. Getz and Odendall, who are working under the patents of Farbaky and Schenek, and of the Electrical Power Storage Company. Each cell is composed of three sections of plates, and weighs altogether

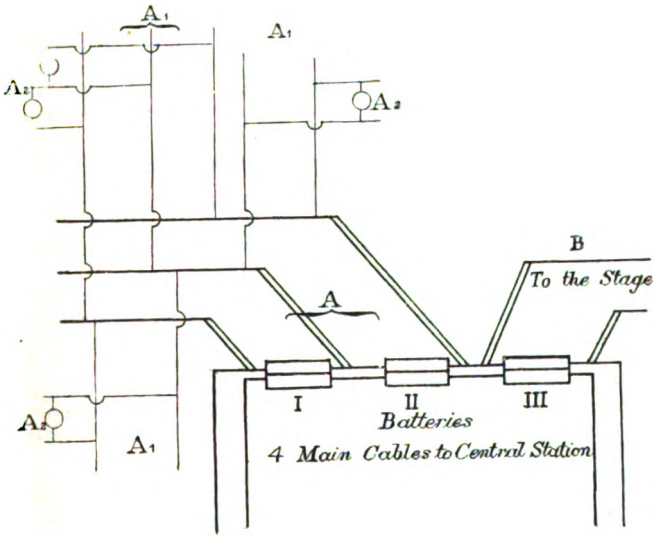

FIG. 1.

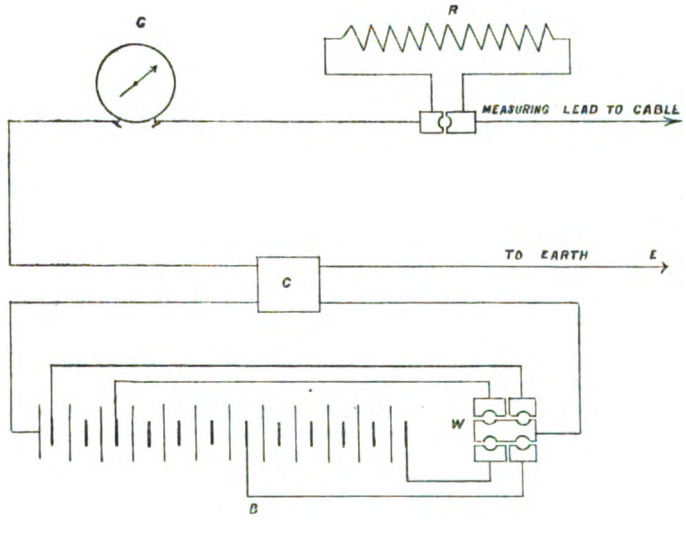

FIG. 2

nearly 300 kilometres. 486 such cells are divided into three batteries, Nos. I., II., III. (Fig. 1), each battery being again subdivided into three series, consisting of 54 cells; there are, therefore, in all nine series of 54 cells each. In this number are included the regulating cells, which are added as required by the fall of potential: this regulation is effected by means of a complete apparatus designed by the engineer of the I.C.G.A.

Battery No. III. is specially for the stage lighting on the simple parallel system B, while the batteries I. and II. are used for the remainder of the house, and all are arranged in connection with a three-wire system, A. These three batteries alone (*i.e.*, without current from the machines) are sufficient to maintain 3,600 lamps of 16 nominal candle-power for six hours. Thr e of Dr. Aron's latest type of electricity meters, one for each battery, register the quantity of current used. The current after passing the meters is conveyed by means of massive cables to the distributing room, and these cables are here connected to the copper bars of the main switch-boards. The different house circuits all start from these boards, each being provided with a switch and double fusible cut-out. To the above-mentioned three-wire system belong 94 leads, and these I have termed distributing leads of the first order, the branches from these distributing leads of the second order, and from these latter are taken the leads to single lamps. The cables which belong to the first order are marked A_1, those to the second order A_2. The total length of leads in the system is about 110 kilometres, and on these are 5,300 incandescent lamps, varying in power from 10 to 40 candles, also 15 arc lamps for the stage and exterior of the theatre.

The auditorium is lighted by means of a magnificent lustre containing 370 lamps and by 16 sun burners; the *foyers*, corridors, and staircases have 1,800 lamps; dressing rooms, &c., 800; while for the stage 1,970 lamps of 25 candle-power are in use. A very complete stage regulating apparatus, constructed by the Allgemeine Electricitäts Gesellschaft in Berlin, allows all the light effects required on a large stage to be produced, including, by means of coloured lamps, sunrise and sunset scenes.

The accumulators in this theatre being sufficient in themselves to supply the current required for a performance gives a security and convenience to the public (in the improbable event of all the machines breaking down) which no other theatre in the world can offer. This magnificent installation does the greatest credit to the Imperial Continental Gas Association and to its engineers, Messrs. Melhuish, Sechehaye and Gardy.

A well insulated wire was permanently laid from the testing room on the ground floor (where the instruments were set up) through the cellars to a point situated as nearly as possible in the centre of the building. From this point the wire was conveyed each time to the portion of the cable under examination by means of a portable reel. The total length of the testing wire was 400 metres; it was a copper wire insulated with gutta-percha and double-cotton covered.

Telephonic communication was established between the test room and the point where the measuring wire was connected to the cable. Finally, an earth wire was brought into the measuring room.

As galvanometer, I selected, with most satisfactory results, the Weinhold mirror galvanometer. I used in most cases 12 well insulated Siemens cells, and for some measurements a chloride of silver battery.

In the accompanying diagram (Fig. 2) the galvanometer is marked G, the battery B. With the help of the switch W, either 1, 3, 6 or 12 cells could be used as required. A commutator, C, allowed the positive pole of the battery to be connected with the galvanometer G, and the negative with the earth wire E, or *vice versâ*.

The second terminal of the galvanometer G remained always in connection with the measuring wire leading to the cable under examination, the withdrawal of a plug allowed a large resistance, R, to be inserted between the galvanometer and the measuring wire. The galvanometer had a resistance of 960ω. I also made use of Siemens and Halske's graphite resistances, one having $5 \times 200{,}000$ ohms, the other with graduations, three of 10 million, one 20 million, and one of 50 million, making together 100 meghoms.

It was ascertained by preliminary experiments how many degrees the Weinhold galvanometer registered if resistance to the amount of 1 megohm was placed in circuit with it. Let s be the number of degrees shown, and n the number of cells in use. If on again connecting the resistance to be measured, x, the degrees shown are s_1, while n_1 cells are employed, the resistance is

$$x = \frac{n_1}{n} \cdot \frac{s}{s_1} \cdot 10^6 \quad \ldots \ldots \quad (1)$$

that is

$$\frac{n^1}{n} \cdot \frac{s}{s_1} \text{ megohm.}$$

The measuring battery did not remain constant, so that these preliminary experiments had to be repeated before each set of measurements was begun. We will here limit ourselves to accounts of averages given in round numbers. One cell of the battery caused a throw of nearly 4 degrees with the megohm resistance in circuit.

Digitized by Google

As on the one hand one-tenth of a degree could be estimated (especially as the commutator was used each time), and as on the other hand 12 cells could be employed, it was possible to measure or rather estimate resistance to the extent of $40 \times 12 = 480$ megohms. If an insulation resistance was so great that no reading could be registered with certainty, even when the whole battery was employed (which was frequently the case), it could be assumed that the resistance must exceed 480 megohms. On the other hand, the smallest resistance that can be measured is 0·08 megohm.

Leads whose insulation was found to be below the above-mentioned limit were then tried with the insulation tester of Siemens and Halske; this is a magneto-inductor with handle combined with a vertical galvanometer. When the handle is turned at a certain speed the scale of the galvanometer indicates the ohms in circuit. This apparatus measures (approximately only, of course) from 70,000 to 10,000 ohms, but by its use a fault can be easily detected, as, in such a case, by turning the handle only slowly the pointer will be thrown entirely off the scale.

When, therefore, it became necessary to measure accurately resistances of less than 0·1 megohm, I used the Weinhold mirror galvanometer with a suitable shunt; this apparatus, however, was not required for single leads, but only when it became necessary to measure groups.

Single leads which showed a resistance of less than 0·1 megohm were noted as faulty, and pointed out to the engineers of the I.C.G.A. to be repaired or replaced.

Every measurement was begun with only one cell of the test battery in circuit in order to avoid damaging the galvanometer in cases where the insulation resistance was low. In order to entirely prevent such damage occurring a protecting resistance of 1 megohm (*see* Fig. 2) was also placed in circuit with the galvanometer; if then it was found that the reading was less than four divisions on the scale, this protecting resistance was plugged out and the number of cells increased as required.

The frequent appearance of faulty leads, even after the extreme care exercised by the Engineers of the I.C.G.A. in applying only the best material and workmanship, is not to be wondered at when one bears in mind, first, that I rejected as bad many leads which in other installations would have been passed as satisfactory. For instance, the Phœnix rules require for single leads an insulation resistance of 10,000 ohms, whereas I rejected all those which did not show at least 10 times this amount; secondly, the conditions under which the installation was made were unfavourable in this respect.

It was necessary to lay several leads in damp walls, and these gave great trouble later; others were removed at my request because they were, in accordance with a clause in the original contract, insulated with asbestos. This insulation, however, on account of its hygroscopic qualities, proved itself unsuitable.

Beyond the three modes of measurement already referred to still a fourth method—with which, however, I only became acquainted shortly before the completion of the work—was used. I mean the method described by F. Uppenborn in the *Centralblatt für Electrotechnic* (No. 22, Vol. 1888), in which a torsion galvanometer is used together with a battery having an E.M.F. equal to the E.M.F. to be used in the installation when it is at work.

The lead-covered cables were supplied by Chaudoir (Vienna), and the India-rubber insulated cables and wires by the London Electric Wire Company and Franz Tobisch (Vienna).

Each lead was numbered and lettered in such a manner that it could be recognised. Before taking each set of measurements the test lead itself was tried, and when this was found to be in order the regular tests were commenced. The lengths of the cables as far as they were known, or could be averaged, were noted down, and to what extent and in what manner they were fitted with their lamps. When a three-wire group of the second order had its lamps in position, it gave, as one might expect, the same value of insulation resistance for all three wires, whether positive, negative, or alternative. The order in which the tests were taken was throughout as follows:—First, all distributing cables of the second order (*see* those marked A_2, Fig. 1) were measured. Amongst these were the asbestos-covered cables in the dressing rooms, of which mention will be found elsewhere, and which were replaced by others later on. Of these distributing leads of the second order the greater part was not fitted with lamps at the time, and could therefore be tested singly. A test was also taken of the large lustre in the auditorium. This has separate cables (of the first order), and was fitted at the time with its 373 lamps. The above distributing leads were later on jointed up to the distributing leads of the first order, and these in their turn to the main bars on the switch-boards (*see* A, Fig. 1). Next, the testing of cables in groups was taken in hand, *i.e.*, the measurement of the insulation resistance of the 94 distributing leads of the first order, composed of 3 and 2 wire sets (in all 34 sets), with their branch wires and lamps, and here the loss on the switch-boards had to be taken into account. Finally, I took the insulation resistance of the two complete groups marked A and B in Fig. 1., *i.e.*, the whole system of cables with the exception of those belonging to the stage, then of the stage itself, and then of the whole network connected up together. In addition to these tests fresh measurements were made of those cables which had been repaired or renewed, so that the total number of individual tests was brought up from 600 to nearly 800.

The above tests can be arranged under three heads, which give at the same time the order in which they were taken, *i.e.*, tests of single cables, tests of cables grouped together, and tests of the whole network of cables as coupled up. With regard to the results obtained, I am, of course, unable to publish the notes themselves, containing as they do particulars of over a thousand tests taken during a period of ten months. I must therefore content myself with giving a few of the principal results. With regard to the measurements of single cable, the insulation, with the exception of those damaged by moisture or other means, as mentioned above, was altogether excellent. Out of about 600 cables which were measured singly the greater part had an insulation resistance of several megohms, many had more than 100 megohms, some even a resistance from 400 to 500 megohms and over.

The great lustre in the auditorium, which carries 373 lamps, supplied through about 250 metres of wire, gave an insulation resistance from wire to metal of 1·4 megohm. The chain by which the lustre is suspended is insulated from the lustre itself, the value of this insulation being 61 megohms.

For the hair curling apparatus a special lead was laid, as on account of the current these required (about the equivalent of six lamps of 16 candle-power for each apparatus) it did not seem advisable to put them on the lighting leads already laid.

Of course the measured insulation resistance of a complete system of cables is always less than that obtained by calculation from the measured resistances of the individual wires which make up the system, because all switches, safety fuses, &c., connected with the cables must inevitably cause an additional leakage of current. A further decrease of insulation resistance is found if the lamps are put on to the wires. To find a mean of the single cables I asked my assistant (Mr. G. Frisch) to take at random a number of the results already obtained, and to calculate the average insulation resistance for a given length of cable. For this purpose the 72 cables leading to the boxes of the theatre, which had given average results, were chosen. An average insulation resistance of 1·7 megohm per kilometre was found. Later on we shall see that when we pass from single cables to a network this average is reduced to less than one-tenth in value.

In the groups described above the insulation resistance may be reckoned at ten thousands of ohms, lying, as it does, between 7,000 and 60,000 ohms, so that we have an average of rather more than 40,000 ohms for one of the 34 groups (each consisting of 94 distributing leads of the first order, with branch wires and lamps). This insulation resistance of the four main switch-boards was about 60,000 ohms, and is therefore the outside limit of the insulation resistance of any group connected up.

Whilst testing single wires I noticed an electric current pass through the slate (the fuse being open), when by accident a wire conveying a current made contact temporarily with the slate. It showed clearly on the mirror galvanometer. Similar observations were made at the main switch-boards, even when only one of the main lines connected with them was in use for lighting.

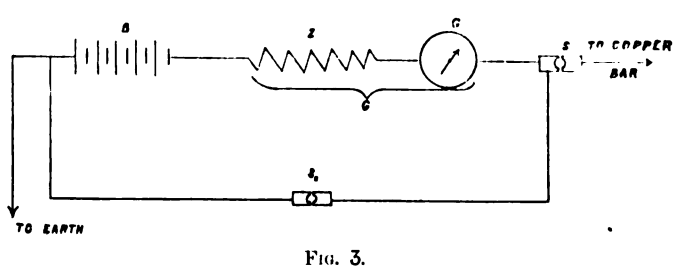

Fig. 3.

The final tests of the whole installation were made as follows:—A small accumulator battery, B (Fig. 3), of 52 cells in series, was used with one of Siemens and Halske's torsion galvanometers, *g*, constructed for strong currents with the necessary resistance box. By means of this extra resistance $Z = 999$ ohms, the total resistance of the galvanometer was made $G = 1{,}000$ ohms, the resistance of the instrument itself being 1 ohm. In this way a deflection of one degree per volt was obtained. The end of the wire, which could be closed or interrupted by means of a plug, S_1, was, the lighting accumulator being disconnected, attached to one of the three copper bars with which the above 94 cables are in connection. The other pole of the measuring battery was put to earth, and between *a* and *b* a shunt was connected which could be closed or interrupted by means of the plug S_2.

The Uppenborn method was employed as follows:—First, S_1 was left open and S_2 closed. Then, neglecting the resistance of con-

Digitized by Google

necting wires, the potential Δ of the measuring battery gives a throw on the magnet, which is then balanced by torsion of the angle ϕ, as shown in the equation

$$\frac{\Delta}{G} = k\phi.$$

If S_2 be opened and S_1 closed, the insulation resistance to be measured is joined up in circuit, and a deflection ϕ^1 is obtained, as shown in the equation

$$\frac{\Delta}{G+x} = k\phi^1,$$

k being in both equations a constant of the instrument.

From the above we have

$$x = G\left(\frac{\phi}{\phi^1} - 1\right),$$

and in this case G = 1,000.

First, the insulation resistance of all the cables was taken with the exception of those in use for the stage. These I shall call the stage circuits in distinction to the other, or house circuits. The house circuits start from three copper bars, to which the three mains from the accumulator batteries I. and II. are connected. It was therefore necessary to interrupt the connection between these mains and the copper bars.

The measuring lead from the torsion galvanometer (*see* Fig. 3) was then connected to one of the three copper bars. The results of the tests were as follows :—

1st test ... $\phi = 109{\cdot}3$; $\phi^1 = 49{\cdot}0$; therefore, $x = 1{,}230$ ohms.
2nd test... $\phi = 108{\cdot}3$; $\phi^1 = 48{\cdot}1$; therefore, $x = 1{,}250$ ohms.

From this we have an average of 1,240 ohms for the total insulation resistance of the house circuits. The length of cable is 100 kilometres. The test of the stage circuits, which are fed by two main cables marked B, leading from the accumulator battery III., was taken in the same manner, and the following results obtained :—

1st test ... $\phi = 108{\cdot}3$; $\phi^1 = 30{\cdot}9$; therefore, $x = 2{,}500$ ohms.
2nd test... $\phi = 109{\cdot}2$; $\phi^1 = 31{\cdot}9$; therefore, $x = 2{,}420$ ohms.

Taking the mean of these we have an insulation resistance of 2,460 ohms for the stage circuits. The length of cable is 10 kilometres. I then coupled up both circuits together, with the following results :—

1st test ... $\phi = 109{\cdot}2$; $\phi^1 = 59{\cdot}2$; therefore, $x = 840$ ohms.
2nd test... $\phi = 108{\cdot}0$; $\phi^1 = 59{\cdot}0$; therefore, $x = 830$ ohms.

So the mean insulation resistance of the whole network, containing 110 kilometres of wiring, is 835 ohms. Taking the insulation resistance of the house circuits as connected in parallel with that of the stage circuits, we have by calculation

$$\frac{1{,}240 \times 2{,}460}{1{,}240 + 2{,}460} = 823,$$

which agrees well enough with that found by measurement. We will compare these results with a formula proposed by Mr. F. Ross for the insulation resistance test of electric light installations, namely :—

$$W = 10{,}000\ \frac{E}{J}$$

where W is the insulation resistance of the whole network, E the difference of potential used, and J the total current employed for lighting.

As previously stated, out of the total number of 5,300 lamps 1,970 serve to light the stage, the greater number of these requiring a one-ampere current. We have, then, for the stage circuits (system B) J = 2,000 nearly, and as the difference of potential may be taken as E = 100, there should be, according to Ross's formula, an insulation resistance of

$$10{,}000\ \frac{100}{2{,}000} = 500 \text{ ohms.}$$

The tests gave a result nearly five times as large, viz., 2,460 ohms.

The house circuits (system A) have about 3,300 lamps. Reckoning these as requiring on the average currents of 0·5 ampere, and adding 100 amperes for ten arc lamps, at 10 amperes a piece (which belong to the house circuits), we have J = 1,750 amperes. The difference of potential is twice that in use on the stage, *i.e.*, E = 200, and we find from the Ross formula the value of the insulation resistance as

$$10{,}000\ \frac{200}{1{,}750} = 1{,}143 \text{ ohms.}$$

The actual measurement, however, gave the far higher result of 1,240 ohms. In comparison with the actual current used, the figures given above are too high, as all the lamps are never burning at the same time. But, in my opinion, not only the number of lamps burning but all those put up should be included under the J of the Ross formula, as it professes to be a test of the whole wiring.

The result for the total network ought to have been (according to the values reckoned above, namely for A and B 1,143 and 500),

$$\frac{1{,}143 \times 500}{1{,}143 + 500} = 348 \text{ ohms,}$$

whereas the actual test gave 835 ohms.

In the book by Killingworth Hedges, on the "Precautions to be Adopted on Introducing the Electric Light," p. 41, we find the rule given that a network of wires should have an insulation resistance of at least 500 ohms per volt difference of potential employed. This would be the more difficult to obtain the greater the extent of the installation, and with a very large installation would be impossible.

The tests would appear far better if judged, not by the Ross formula, but by that of the Electro-Technical Society, in which the coefficient 5,000 is used instead of 10,000. The results of the final tests would then satisfy the strictest requirements.

As far as I am aware, this is the most comprehensive and exact examination of this kind yet made, or at least published.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-night) FRIDAY, February 15th.

SOCIETY OF ARTS.

8 p.m. Indian Section, "The Ruby Mines of Burmah." By G. SKELTON STREETER, F.R.G.S.

ROYAL INSTITUTION.

9 p.m. Evening Discourse, "Electrical Stress." By Prof. A. W. RÜCKER, M.A., F.R.S.

SATURDAY, February 16th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture, "The Character of the Great Composers and the Characteristics of their Works." By Prof. ERNST PAUER.

SATURDAY LECTURE SOCIETY.

8 p.m. Lecture in the Lecture Theatre of the South Kensington Museum, "Hypothesis of the Meteoric Origin of the Heavenly Bodies and the Earth" By Prof. J. NORMAN LOCKYER, F.R.S.

MONDAY, February 18th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture III. 2.—"Wood Engraving." By W. J. LINTON.

TUESDAY, February 19th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture, "Before and After Darwin." By GEORGE JOHN ROMANES, M.A., F.R.S.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. "Alternate-Current Machinery." By GISBERT KAPP, A.M.I.C.E.

SOCIETY OF ARTS.

8 p.m. Foreign and Colonial Section. "Slavery in Relation to Trade in Tropical Africa." By Commander V. LOVETT CAMERON, C.B., R.N.

ROYAL VICTORIA HALL.

8:30 p.m. Lecture, "A Chapter in Darwinism. By Dr. W. D HALLIBURTON.

WEDNESDAY, February 20th

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Ordinary Meeting. Papers to be read, "Report on the Helm Wind Enquiry, by W. MARRIOTT, F.R.Met.Soc.; "An Atmospheric Sketch," by F. A. VELSCHOW, F.R.Met.Soc.; "The Drought in New South Wales in 1883-4, and Rainfall at Corella, 1879-88," by the Ven. Archdeacon WYNNE, F.R.Met.Soc.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "The Forth Bridge." By BENJAMIN BAKER, M.I.C.E.

THURSDAY, February 21st.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture, "The Venom of Serpents and Allied Poisons." By SIDNEY MARTIN, M.D., B.Sc.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary Meeting. Paper not decided on.

FRIDAY, February 22nd.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. "Furnaces." By T. A. GUYATT, Stud.Inst.C.E.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Concert at the St. James's Hall Restaurant. Ladies' Night.

ROYAL INSTITUTION.

9 p.m. Evening Discourse, "In the Heart of the Atlas." By HAROLD CRICHTON-BROWNE, F.R.G.S.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714.

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
„ Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1888, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY.

CONTENTS OF THE CURRENT NUMBER.

"THE ELECTRICAL WORLD" IN THE UNITED KINGDOM.

Arrangements have been made by which "THE ELECTRICAL WORLD" OF NEW YORK *can be obtained from* "THE ELECTRICIAN" *Office, 1, Salisbury-court, Fleet-street, London, E.C.*

The Rate of Subscription (payable in advance), including postage, is **£1 1s. 0d.** *per annum to this Country and Abroad.*

Single Copies of "THE ELECTRICAL WORLD" *can also be obtained,* **price 6d. each.**

"THE ELECTRICIAN" IN THE UNITED STATES.

Similarly, "THE ELECTRICIAN" *can be obtained in America at the Offices of* THE W. J. JOHNSTON COMPANY, LIMITED ("THE ELECTRICAL WORLD"), *168 to 177, Potter-building, New York.*

"THE ELECTRICIAN" *can also be obtained from* THE D. VAN NOSTRAND COMPANY, *23, Murray-street, and 27, Warren-street, New York.*

The Rate of Subscription for American Subscribers (payable in advance) is $6 per annum.

Volume XXI. of "The Electrician" is NOW READY,

Price 12/6, post free 13/6.

Cases for Binding Volume XXI. are also Now Ready, Price Two Shillings, Post Free, Two Shillings and Threepence.

LITIGATION AND ARBITRATION.

Not the least of the many advantages which Chambers of Commerce have conferred on the mercantile communities of this country is the system of arbitration provided for disputants who would otherwise resort to the Courts of Law. Trade disputes are peculiarly susceptible of treatment by arbitration, the parties being for the most part actuated by no personal feeling, and having no litigious motives such as commonly give rise to actions at law. Generally the point in dispute is one of assessment of damages, apportionment of charges, or definition of rights; and when business men differ in their relations on such matters as these their last desire is to appeal to the law, which not improbably will swallow up as much money as the item in dispute is worth. Of late years therefore, and chiefly owing to the exertions of these Chambers of Commerce, arbitration has rapidly grown in favour, and has even found a place in the Law Courts themselves, Official Referees, as they are called, being now the recognised instruments for dealing with matters either too intricate or too

Digitized by Google

technical for the ordinary Judges to deal with, or so free from legal difficulty that the Court's time need not be wasted upon them. It is now quite common for Judges to refer to arbitration cases which involve no point of law, and the practice it may be hoped will be still further extended. But for many of these actions the Chambers of Commerce have long been open, and the simplicity and inexpensiveness of their procedure, together with the special fitness of their arbitrators, afford an attractive and unexceptional substitute for any lawsuit to which the parties might otherwise be compelled to appeal.

It will be of interest to the electrical trades to learn that the London Chamber of Commerce possesses a permanent Arbitration Committee, whose object is to facilitate the settlement by arbitration of "disputes arising out of commercial transactions," and whose duty it is to consider, first, whether the case brought before them is suitable for such reference, and then, if desirable, to name one or more arbitrators specially qualified to deal with it. The selection is made from the Section representing the trade to which the dispute pertains; but the assent of the disputants to the nomination is, of course, obtained as a preliminary; and when this has been settled the arbitrators proceed with the investigation. It would seem, though the wording of the bye-law is not quite clear on this point, that one of the disputants may even proceed without the consent of the other, and the arbitrators decide the case *ex parte*. This will perhaps rarely occur; but we can easily see the advantage of submitting to arbitration, even if nothing comes of it, should the case be carried by the dissenting party to a Court of Law. He has, however, another remedy by way of appeal to the Chambers' Permanent Committee, the fee for which is heavier, but the decision of which is final, no case being referred to that Committee unless both parties agree to be bound by its ruling.

By throwing in their lot with the London Chamber of Commerce the electrical trades have secured for themselves and allied industries—for the system is not confined exclusively to members—the advantages of this admirable method of settling their differences. Many of these will fall naturally under the head of "disputes arising out of commercial transactions;" but some others which are of a more technical character may very well come to be regarded as covered by that definition. Of these latter many at least of the actions relating to electrical patents which are continually occupying the attention of the Law Courts might certainly be so treated, at all events in their initial if not in their final stages. Litigation in the majority of these cases would have been averted had the parties been able to appeal with confidence to such a body of men as are now available as arbitrators attached to the London Chamber of Commerce, and we suspect that the final decisions in every case would have been quite as satisfactory to everybody concerned as are those now being delivered in the Courts of Appeal. In the matter of costs they would have been infinitely more satisfactory; and as regards technical and practical knowledge hardly less convincing. It has often been argued that the Patent Office, which grants the patent, should determine its validity when challenged. If ever that argument is acted upon, a jury of experts will be the kind of authority called into play; and, meanwhile, this is precisely the jury we possess, though without legal status, in the Trade Sections and Arbitration Committee of the Chamber of Commerce. The requisite binding force of its decisions is obtained by a formal undertaking entered into by the disputants, effectually preventing any subsequent legal proceedings on the specific matter in dispute. It is here that arbitration has such vast superiority over the law, the uncertainty of whose decisions and the unlimited openings it affords for further proceedings being a continual temptation to persevere in a course of litigation which would be ruinous if stopped, and can only mean ruin if it fail.

That this is a tolerably fair description of some of the patent cases which for years have been encumbering the Law Courts nobody who carefully follows our reports can fail to have seen. Nor can it be doubted that, generally speaking, the merits of the essential points in dispute would be more equitably adjudicated upon by independent experts than by legal adepts, whose object it is to win a case whatever its merits or demerits may be. Of the Judges we cannot speak too highly, the labour they bestow in discharging a thankless and alien task being as surprising as it is praiseworthy. But they have to rely upon the Bar to "inform" the Court, and not in every case are members of the Bar competent, even if they are willing, to perform this necessary duty. It sometimes happens, as in a quite recent suit, that the judges have to complain that they are *over much* informed, the statements and arguments being spun out to such inordinate length that the gist of the matter is buried under mountains of rhetoric. In the case referred to Lord Justice LINDLEY, one of the Appeal Judges in *re* Gaulard and Gibbs's Patent, declared that ten days had been occupied with what need only have taken up four. His lordship would have been nearer the mark, regarding the case from our point of view, if he had said as many hours as it had occupied days. For we suppose nobody will deny that, not in this case particularly, but in all similar cases brought before the legal tribunals, the technical features are manipulated in such a way as to puzzle even the most conscientious of laymen, and are so mixed up with legal subtilties as to mislead even the most learned of lawyers. The evil grows apace as these cases become more numerous, and if not speedily abated will inflict irreparable injury upon every industry that depends on the integrity of patent rights. To electrical industry especially it has done grave mischief already; and on this account we look with hope to the alliance of electrical trades with the London Chamber of Commerce as a means of settling these disputes in the first instance, and preventing them being handed over to the legal profession whose interest it is to unsettle them.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

SECTION III.—MAGNETIC FIELDS OF COILS AND SOLENOIDS.

(Continued from page 403.)

145. *Intensity of Field in the Region of a Circular Current. The C.-G.-S. Unit of Current.*—In the preceding paragraph we investigated the direction of field along the axis of a ring conductor carrying a current, and that direction we considered in one plane only of the ring. What is true for one plane is true for all sectional planes of the ring, and a little consideration will show that the *entire* magnetic field (or force on unit pole) set up at a point on the axis, that is, the field due to the current in the ring conductor, *as a whole*, will be acting at the point round a cone-like surface. This effect of the entire field at the point may be understood by the perspective view of the ring and the forces set up by it at the point p in Fig. 133. Here A B is the axis of the ring as before, and if we imagine a unit north pole at the point p, it would be urged outwards from the ring along the axis towards B. In this direction there must evidently be one resultant force equal to the combined forces acting round the cone at the point, and it is this resultant that we have to find. Now, any point on the axis A B is equidistant from every portion of the ring conductor; and when this is the case the *total* intensity of

Digitized by Google

field at the point is directly proportional, by Ampère's law, to the length of conductor multiplied by the strength of current, and inversely proportional to the square of the distance between the point and conductor. The distance between any point on the axis and the conductor is simply the common radius to all those circles of force which pass through the point. If we take R as this radius, C as the current, and L as the length of conductor composing the ring, the total intensity of field at the point is proportional to

$$\frac{C\,L}{R^2}.$$

Now, to find the resultant of this field along the axis, let us consider one plane through the cone, as before. Here

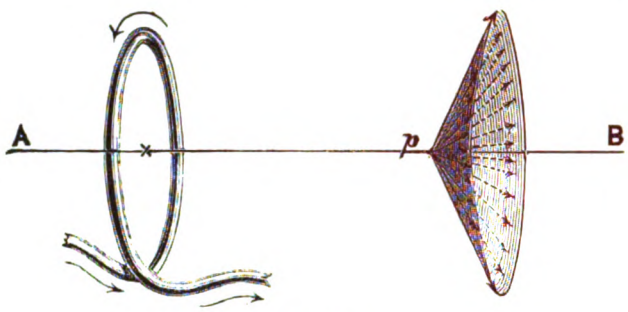

Fig. 133.

we have two diametrically opposite forces, each, say, equal to F (Fig. 134), acting at the point p, as tangents to the circles of force through the point, or in other words, at right angles to the common radius R, of the circles of force through p. Completing the parallelogram of these forces, and calling f the resultant of the pair, we find by similar triangles that

$$f : F :: 2r : R,$$

where r is the radius of the ring conductor whose opposite sectional portions are at W W, that is,

$$f = F\frac{2r}{R}$$

Now it is evident that the resultant of the whole cone of forces bears the same relation to the combined intensity of

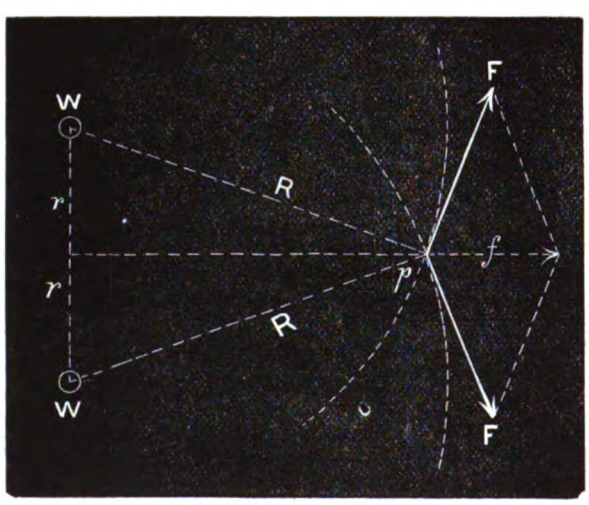

Fig. 134.

those forces as the resultant (f) of the pair (2 F) bears to that pair. Therefore we have the relation,

$$\frac{\text{Resultant field}}{\text{Total field}} = \frac{f}{2F}.$$

Substituting the value of f as obtained above, and cancelling, we have

$$\text{Resultant} = \text{total field} \times \frac{r}{R},$$

$$= \frac{C\,L}{R^2} \times \frac{r}{R}.$$

Now, the length of conductor (L) in a ring of radius r is equal to $2\pi r$, and therefore we have,

$$\text{Resultant along axis} = \frac{C\,2\pi r}{R^2} \times \frac{r}{R},$$

$$= \frac{2\pi C r^2}{R^3}.$$

This is a very important expression, as it is proportional to the field at any point along the axis of a coil. We have not yet taken the quantities in any fixed system of units, so that the expression as it stands must be regarded as simply proportional to the field.

Now in this expression we notice that the numerator is constant for a given current flowing in a ring of given size, and the field at any point along the axis of the ring is inversely proportional to the cube of the radius of the circles of force through that point, that is, the cube of the distance of the point from the conductor.

It is interesting to represent graphically the rate at which this field decreases as we take points further and further from the coil. All that is necessary is to take measured distances along the axis A B of the coil (Fig. 135), starting from 0 at the centre of the coil, and for each of these distances calculate the radius R, then cube it and take its reciprocal, the resulting number being proportional to the strength of field at the points taken. For instance, taking the radius of the ring as unity, and the strength of field at its centre as 1,000, we find

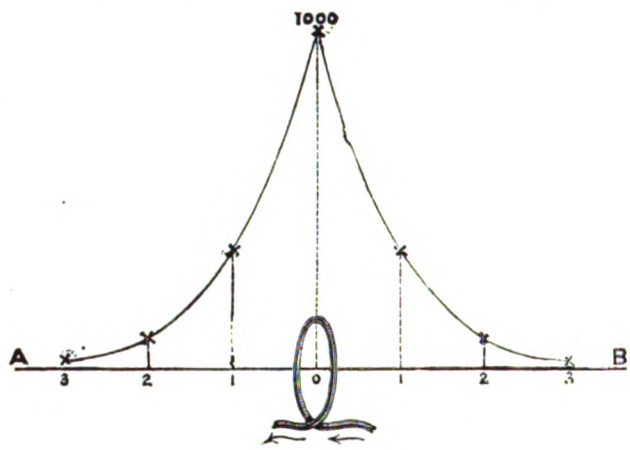

Fig. 135

that at the distances one, two, and three the field is proportional to 350, 89, and 32 respectively. It will be noticed in Fig. 133 that R forms the hypothenuse of a right-angled triangle, of which one side is the radius (r) of the ring, and the other is the distance (d) of the point on the axis from the centre of the ring. We have, therefore, the relation (Euc. I., 47)

$$R^2 = r^2 + d^2$$

whence

$$R^3 = (r^2 + d^2)^{\frac{3}{2}},$$

from which the cube of the radius R may be found for any distance from the centre of the ring. Raising vertical ordinates proportional in height to the field at the several points chosen, and connecting them, we obtain the curve in Fig. 135, showing the rate of decrease of field on each side of the ring along its axis.

It will be seen that at the centre of the ring R is equal to r, and therefore the field is proportional to

$$\frac{2\pi C}{r}.$$

Now, in the relation of these quantities there are two, viz., intensity of magnetic field and length, which have already been defined, and units fixed on the absolute C.-G.-S. system. There is one quantity, viz., the current, of which we have not yet exactly defined an absolute unit. If we make C and r equal to unity in the above relation, the strength of field at the centre of the coil becomes numerically equal to 2π, and expressing the strength of field in C.-G.-S. units, we can define the unit of current on the C.-G.-S. system as that current which, flowing in

Digitized by Google

a circular conductor of one centimetre radius, produces at the centre of the coil a magnetic field equal to 2π C.-G.-S. units. The practical unit of current, to which is assigned the name of Ampère, is chosen as equal in value to *one-tenth* of the absolute unit, and therefore one ampere flowing in a ring conductor of one centimetre radius produces a field of

$$\frac{2\pi}{10}, \text{ or } \frac{\pi}{5} \text{ C.-G.-S. units.}$$

If the ring or coil consists of more turns than one, say n turns, the field is increased n times, and the complete expression for the field at any point becomes

$$\frac{2\pi C n r^2}{R^3} \text{ C.-G.-S. units,}$$

where r is then the *mean* radius of the coil in centimetres.

Example.—The coil in Sir Wm. Thomson's graded current galvanometer (described para 132) consists of six complete turns of stout copper strip, the inside diameter being 6 centimetres and the outside 10 centimetres. What is the intensity of field produced by a current of 30 amperes flowing through the coil, at a distance of 10 centimetres from the centre of the coil along its axis, and what is the field produced at the centre of the coil?

Mean radius of coil (r) $= 4$
Current in C.-G.-S. units (C) $= 3$
Number of turns (n) $= 6$
$2\pi C n r^2 = 1809{\cdot}5$
log of $1809{\cdot}5 = 3{\cdot}25755$

$R^3 = (r^2 + d^2)^{\frac{3}{2}} = (16 + 100)^{\frac{3}{2}}$
log of $116 = 2{\cdot}06445$
log of $R^3 = \frac{2{\cdot}06445 \times 3}{2} = 3{\cdot}09667$

Subtraction gives log of answer $= {\cdot}16088$

Therefore,

Intensity of field $= 1{\cdot}448$ C.-G.-S. units.

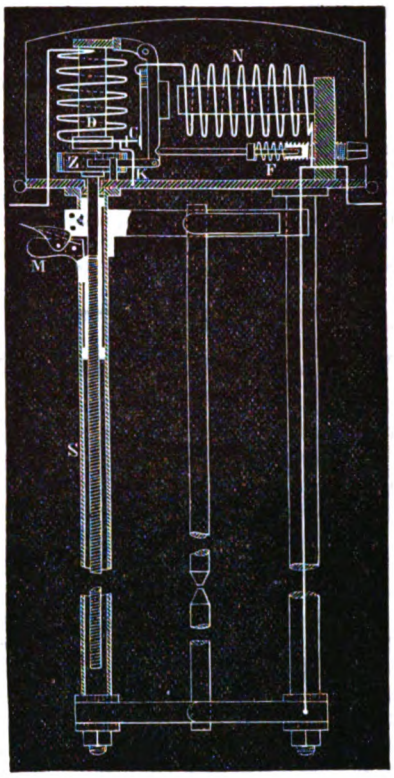
Field at coil centre $= \frac{2\pi C n}{r}$ C.-G.-S. units.

$= \frac{56{\cdot}55}{4} = 14{\cdot}14$ C.-G.-S. units.

(To be continued.)

THE SIEMENS ARC LAMP.*

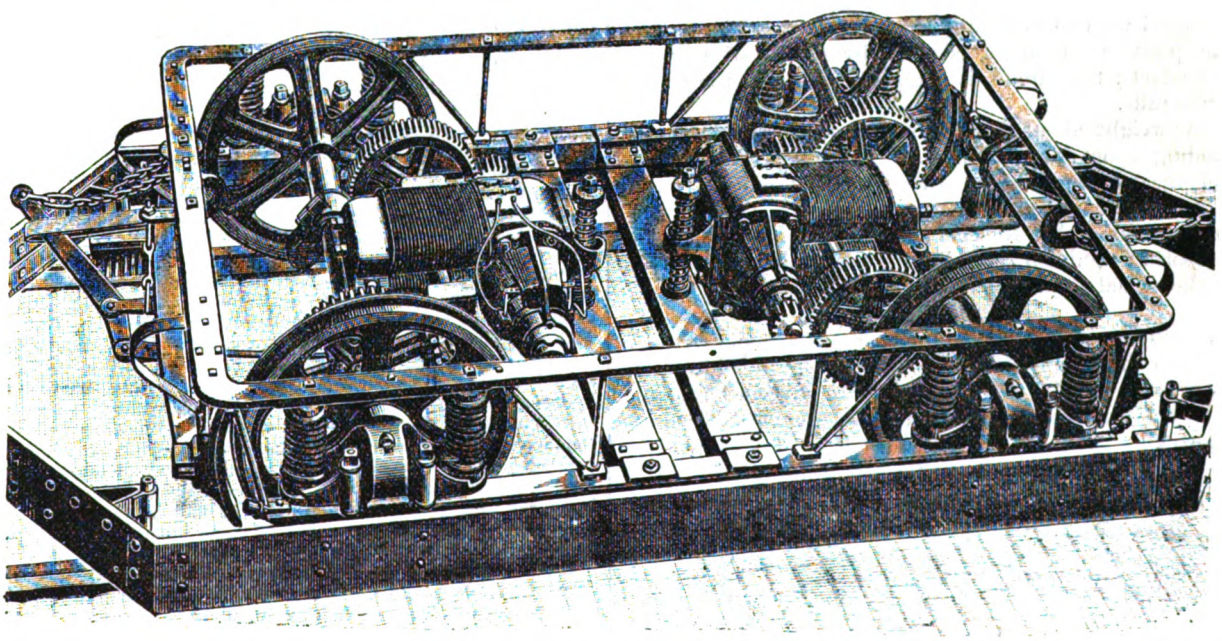
The accompanying figure represents the latest (1886) type of the well-known arc lamp manufactured by the firm of Siemens and Halske. There are two electro-magnets, D and N, wound with thick and thin wire respectively, D being used to strike the arc, and N



to regulate its length. The electro-magnet N is provided with a trembler, C, which actuates the toothed wheel Z, and in this way turns the screw S, contained in one of the rods of the lamp. The

* Translated from M. Hippolyte Fontaine's "Eclairage à l'Électricité," by permission of the author.

SPRAGUE MOTOR TRUCK FOR STREET CARS.



The adjoining engraving shows the latest design of Mr. J. T. Sprague for tramcar trucks. Each motor is of 15 horse-power, and is geared to the axles through an intermediate shaft, which passes between the field-magnets. The small pinion on the armature shaft has teeth of vulcanised fibre. The motor is swung from the axle on one side, and flexibly supported on the other. Everything is designed to reduce the care and attendance to a minimum; all bearings are self-oiling and dustproof, and each is removable.

Digitized by Google

upper carbon-holder slides between the two vertical rods, and by means of the little mechanism at M, it can be made to engage with the screw S, so as to descend as the screw turns. When the current traverses the lamp, the wheel Z, which acts as armature to the electro-magnet D, is attracted, and lifts the positive carbon. The wheel Z is made thick enough to prevent the detent K quitting it when Z is attracted by the magnet. If the arc becomes too large, the electro-magnet N attracts its armature and actuates the trembler C, which is simply a little electric motor similar to that employed in the original Siemens lamp; but with this difference: in the original lamp the carbons were pulled apart when they approached one another too closely under the action of gravity, while in the present type of lamp the carbons are made to approach as soon as the arc becomes too long. A screw on the outside of the lamp permits of the spring F being regulated as desired. When recarboning the lamp, M is unbraked, allowing the upper carbon holders to move freely.

This lamp is a happy combination of the old pattern Siemens and the Cance lamp. The mechanism is compact and simple, and all the essential parts are well constructed. The carbon clips, however, seem somewhat too large to allow of very accurate allignment of the carbons.

RYDE PIER ELECTRIC RAILWAY.

Although the electric railway on Ryde Pier cannot be described as an engineering enterprise either of great magnitude or of profound difficulty, yet, as one of the earliest electric tram lines in this country, and one which both technically and commercially has given entire satisfaction from the very first, a brief description of the arrangements adopted will be of interest.

The line is on the level throughout, without curves, and is 716 yards long, the gauge is 4ft. 8½in., and there are two sidings. The generating plant consists of a 12 horse-power Otto gas engine, driving a Siemens S B_8 dynamo, at a speed of about 1,000 revolutions per minute, when it gives a current of 60 amperes with an E.M.F. of 120 volts. The current is conveyed from the engine-house by underground cables to the tram line. As the line on the pier is entirely fenced off from the public promenade, a bare channel-iron by the side of the line is used as a positive conductor, the tram-rails serving as a negative conductor. The channel-iron is carried on insulators attached to cast-iron brackets, which are bolted to the sleepers. The total resistance of the line is 0·275 ohm.

The motors are of the Siemens horizontal type, D_2, fixed under the cars. The transmission is effected by means of a pitch-chain. Each D_2 motor is sufficiently powerful to propel its own car and a second one attached thereto. The motors are each fitted with starting and reversing gear. The contact with the positive conductor is made by means of a spring rubbing contact; the circuit is completed through the wheels to the tram-rails.

Each car weighs about 5 tons; it has seats for 18 persons, and standing room for 12 more. The cars are lighted by means of incandescent lamps, the necessary current being derived from the main conduits.

By the courtesy of Mr. Roberts (the Secretary and Manager) we are enabled to publish the following comparative statement, showing the actual results of working by horses and by electricity.

It is as well to note that the number of passengers carried is obtained from the number of tickets issued, but in addition to these all persons holding railway tickets to or from Ryde, and all persons holding passes and free tickets, are entitled to use the tram-cars.

Half-Year ended 31st December, 1885.

TRAM-LINE WORKED BY HORSES.

Hire of horses and drivers	£ 34 0 0	
Conductors' wages	31 4 0	
Repairs and incidental expenses	10 0 0	
Oil for lighting cars	1 10 0	
		£176 14 0
Cash Receipts	£350 18 7	
Passengers carried	72,802	
Train miles	5,258	

Receipts per train-mile, 15·9d. Expenses per train-mile, 8·02d.

Half-Year ended 31st December, 1886.

TRAM-LINE WORKED by ELECTRICITY.

Gas consumed in engine— 289,200 feet (cubic) at 3s. 11d. per 1,000, less 5 per cent.	£53 16 0	
Wages of conductor and boy	39 16 0	
Wages of engine driver and assistant	64 6 6	
Repairs and incidental expenses	15 18 7	
		£173 17 1
Cash Receipts	£532 2 1	
Passengers carried	113,733	
Train miles	6,435	

Receipts per train-mile, 19·9d. Expenses per train-mile, 6·48d.

ELECTRIC METERS FOR CENTRAL STATIONS.*

(Concluded from page 396.)

DISCUSSION.

The CHAIRMAN called upon Mr. Swan to open the discussion, but that gentleman having to catch a train, promised to send a written communication to the Society on the subject of the Paper.

Mr. CROMPTON was then called upon. He regretted that Mr. Miller was not present to speak, as it was owing to that gentleman that the meter they used (the Aron meter) had been so successful, many of the alterations which had been made in it being due to his perseverance. They had not always used the Aron meter; but had commenced with another which was not so satisfactory. The latter was superseded by an Aron meter in its original form, with a clock which was started when the current was turned on. Its heat, however, gave endless trouble. Suggestions were made, which resulted in the invention of a single clock which they were now employing, and which he believed ran up to 30 days. The many difficulties attending Aron's meter had now been removed. He had recently spent some considerable time in Berlin, where he had had opportunities for carefully inspecting the whole of the system. He believed they were now perfectly satisfied with the meter, but he thought that only the current used by incandescent lamps was registered. The success of the Berlin system entirely depended on the arc lamps, as there were very few incandescent lamps in that city. There was a company at Liverpool which was also working largely by meter. They had introduced one made by Chamberlain and Hookham, which he believed was as accurate as Aron's meter, and in some points was superior to it. He agreed with Prof. Forbes about the Edison meter; there was infinitely more real work done by it than by any other meter in use, and its accuracy was astonishing. At the time Mr. Ferranti brought out his meter, Mr. Kapp and himself were experimenting on a meter very much like Ferranti's, which they carried up to the point Ferranti did, but Mr. Ferranti was just a few days before them. Certainly Mr. Kapp did invent a meter which was in every way almost identical with Mr. Ferranti's. In considering the question of candle-power they must remember that English people lived more at home than the Germans or the Americans. We have consequently heavy bills to pay for lighting the hall, passage ways, &c. For our purposes, therefore, a unit of eight candles answered extremely well. No one who saw such a light objected to its being very small, and there was no one who had seen the sixteen-candle lamps sent out by the Edison and Swan but admitted that they were too big for this purpose. His customers bought a small lamp; more than three-fourths of his lamps and those of his customers were small. He believed the experience at the Grosvenor Gallery was very much similar. In shops, clubs, and hotels no doubt the larger light was more satisfactory. If they wished to make the electric light spread and did not wish to frighten people by the cost of the electricity, they ought rather to encourage the use of small lamps (applause). The Leipziger Strasse Station at Berlin was a triumph of spending money; there was no doubt that in England the same thing could be done with equal efficiency for less money (hear, hear).

Prof. AYRTON said they had listened to a most interesting Paper, delivered in a most interesting way. Considering that the author was the inventor of an extremely pretty meter, they must admire the modesty with which he had described his own meter. He would like to break a lance with the author with reference to his remarks as to whether they should charge by quantity or by energy. People were somewhat influenced by the meters they had to supply, and they naturally liked that people should pay for a thing which their meter would measure rather than that the meter should measure the thing they ought to pay for (laughter). No doubt if it were possible to maintain a perfectly constant potential difference between the supply mains, the total quantity of electricity supplied in a given time was all that they need consider or pay for. But let them take things as they were. Is that constant difference of potential maintained? Prof. Forbes even admitted a four or five per cent. variation.

Prof. FORBES: A total variation up and down of two or three.

Prof. AYRTON said he would take it at 2½ per cent. variation. True that only meant 2½ per cent. variation but it meant more than that in the watts, as the resistance of the filament diminished as the volts increased—and think what it meant in the light. The light was what they bought. Speaking as a private person, knowing nothing whatever

* A Paper read before the Society of Arts on Jan. 23, 1889, by Prof. G. Forbes, F.R.S. (See *Electrician*, Feb. 1 and 8.)

Digitized by Google

about electricity (laughter), but having incandescent lamps in his house, he did not care anything about watts or volts or amperes, or any technical units; but what he did care about was this—he bought light, and he wanted his meter to measure more or less approximately what he was paying for. A drop of 2½ per cent. in the volts (it was a great deal more in practice) meant a very considerable drop in the light. The light given out by an incandescent lamp was about proportioned to the cube of the volts minus a constant, as Prof. Perry and he had shown some years ago, so that a variation of three or four volts in a hundred meant a very considerable variation in the light. Nobody admired more than he did the success that the Grosvenor Gallery Company had attained, and the enterprise they had shown in getting over all kinds of difficulties; but at the moment he had nothing to do with that—he was a buyer of light. He was recently at the St. James's Hall, at one of the Saturday afternoon concerts, when during the performance the lights went down so much that the gas had to be all turned up. Supposing they were paying simply by current, they would pay perhaps not very much less than if the right voltage was maintained between the terminals. Supposing that they turned on a few more lamps, so that the total current was the same as it would have been if the right voltage had been maintained, then the bill would be identically the same; but the light obtained was nothing like the same. The light obtained was so little that they had to turn on the full amount of gas, and during that half-hour or so they were actually paying the full gas bill and probably the full electric light bill. Nothing more was needed to show that what the meter ought to measure was what they paid for, and not what they would like to have to pay for. He would go even farther in the opposite direction, and say "Not merely will I measure watts, but I should like the instrument to measure a higher power than the first of the volts into the current." There is one point about simplicity of testing which Prof. Forbes, having so much to say, did not refer to, and which exists with retarded clock meters, but does not exist, he thought, with any other meters. During the time that they were not using electricity they could check the accuracy of the retarded clock meter, because, if they had a simple clock which was retarded when the current was supplied, of course it ought not to be retarded when no current was supplied. All they had to do, therefore, was to compare the going of the ergmeter with the going of a respectable watch; and that in itself formed a very efficient check on the accuracy of the instrument. Any other of these meters (which might be called for simplicity motor meters) could not be tested in that way, because they only worked when the current was started. There was also one way, which his colleague and himself proposed some years ago, of getting over the possibility of cheating. He referred to their ergmeter, which measured the product of current into volts. By putting a magnet near the clock the consumer could no doubt prevent it being retarded so much; and what they proposed to do was occasionally to reverse the current in the whole system, which by a simple arrangement could be accomplished. The result of that would be that anybody who tried to cheat by putting a magnet near would be just as likely to raise his monthly bill as to lower it (laughter and applause). He agreed with Prof. Forbes's remarks as to the objections to contacts in meters. There was one form of meter (also an ergmeter—a motor ergmeter), which Prof. Perry and he had patented some seven years ago, which had a contact—had two contacts, in fact—but he did not think it was open to objection, at least not to the same extent, on that account. It was a motor, the field-magnets of which were wound with thick wire, and there was a continuous circuit through them—no make or break at all. The rotating armature was wound with very fine wire of very high resistance, and there were two brushes to lead the shunt-current through the armature. Any slight change in the resistance of those brushes made but very little difference in the total resistance of the shunt circuit. There were no brushes in the direct circuit, and therefore a little change in the resistance made no change in the accuracy of the instrument. Dirt accumulating year by year under the brushes introduced very little error. With reference to the question of fluid friction, Prof. Forbes had spoken of the force being proportional to the square of the velocity; but surely there must be some mistake in that. With small velocities the retarding force was not proportional to the square, but to the first power of the velocity—a velocity such as existed in Prof. Forbes's very beautiful instrument when the vanes were moving. Those vanes were not moving much faster than the needle of a ballistic galvanometer. The whole calculation of the damping in the ballistic galvanometer depended upon the assumption that the retardation was proportional to the first power of the velocity. He did not, therefore, follow Prof. Forbes's reasoning as to the square of the velocity, and did not agree with the conclusions he had drawn, starting with the wrong hypothesis. While on this subject of fluid friction he was led necessarily to refer to what appeared to him to be the defect of all motor meters. It was this very defect which had prevented his colleague and himself from improving and putting forward prominently (beyond mere publication) their motor ergmeter. They wanted simply to have fluid friction, they did not want solid friction—they must not have the friction of the mechanism. Therefore one was obliged to reduce the dials, the recording mechanism, to very minute dimensions. He understood from Mr. Ferranti that that had been the great difficulty with his meter; if he had no recording mechanism whatever then his meter would be perfect, but it was the friction introduced by the dial mechanism which had made the enormous difficulty in his making his meter successful. The clock-meter had no such defect. There the mechanism was not driven by the current. It was a defect in one sense that they had to introduce another motive force; but introducing that other motive force, namely, a weight or tension of a spring, entirely got over the difficulty. The friction of the mechanism was made up for by the force of the spring, and the solid friction then introduced no more inaccuracy than the friction of ordinary wheel work introduced in a good chronometer. Let them look at the dial in Aron's meter, and compare its large size, its clearness, with the necessary smallness of the dial either in the Ferranti meter or in the very beautiful meter of Prof. Forbes. His colleague and himself owed a debt of gratitude to Dr. Aron for the way in which he had carried out their principle and pushed it so thoroughly in different parts of the world, and as Dr. Aron's agent had wisely recognised commercially their claims to priority of invention, there was perfect accord between them.

He was a little surprised at the success of the Lowrie-Hall meter, because it was based on the assumption that an alternating current when passing through a voltameter or electrolytic cell produced no decomposition. That experiments had shown to be an extremely difficult condition to arrive at. One would think at first sight that if an alternating current were sent through a voltameter there would be no gas whatever produced, but so far from that, one could get a considerable amount of gas produced with an alternating current. For instance, copper could be deposited with an alternating current making many thousand alternations per minute. That seemed a difficulty, but he was delighted to hear that that difficulty had been successfully overcome. A meter for direct or alternate currents on the same principle as that modestly described by Prof. Forbes at the end of his Paper was made at the beginning of last year by Mrs. Ayrton. In that meter water was evaporated by the passage of the current, the water then fell through the tube, and, according to Mrs. Ayrton's design, worked a recording mechanism, and was finally carried back to the reservoir to be re-evaporated.

Mr. SHOOLBRED said the nominal output of an installation ought not to be measured by the number of lamps, because they found that more and more persons were asking for 30 and 100 candle lamps, and even higher—not to speak of various other uses of a current. It was much better to speak of the relative value of an installation in watts or in amperes. It must be remembered, too, that meters were likely to be placed in cellars.

Mr. SMART said the cost of a meter was an important question for tradesmen.

Prof. FORBES, in reply, said he was quite unaware of the Chamberlain and Hookham meter; he had seen their names in a patent, but he had not been aware that the meter was doing sound good commercial work. The costliness of the station at Berlin was hardly within the scope of his Paper, but he hoped to have an opportunity of saying a word about it elsewhere. Prof. Ayrton said that those who make meters do not make them to satisfy the wants of the customers, but tried to make the wants of the customer satisfy the performance of the meter. Prof. Ayrton's meter measured ergs, and he said: "There is no doubt about it, the ergs are the proper things for you to measure," though he admitted that ergs were not a true measure of the light. Now, he (Prof. Forbes) said the coulombs were the things to measure the total quantity of current passed through. Prof. Ayrton said: "Not so; when my lamps are burning down very low it is a great shame that I should be charged almost as much as when they are burning quite bright." Assume that he (Prof. Forbes) wanted to have lights supplied to his house by meter, and that the people were going to charge him by ergs, those people would of course be always wanting to put on a greater pressure than he wanted, and they would be continually breaking his lamps. Not only would he be injured by having his lamps broken, but he would be insulted by being asked to pay more in his meter account (laughter and hear, hear.) He thanked Prof. Ayrton for his reference to another inventor who had been working on the lines of evaporation. A great number had been trying it, but he had not seen another one yet which had made the results proportional to the current going through the meter, and he was sorry that Prof. Ayrton had not explained whether that was done. In reply to Mr. Smart, he had very little knowledge about the cost of the different meters. In America the general idea was that the cost ought to be about a pound or so, at any rate to manufacture, and ten dollars, or something of that sort, the selling price. He did not think the process of manufacture was likely to bring them down so low as that in this country. He should think meters would be selling here in the immediate future for from £4 or £5 up to £18 or £20.

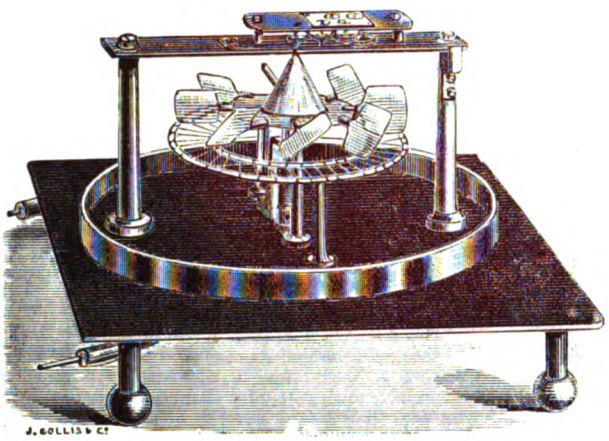
The CHAIRMAN (Mr. W. H. Preece) then proposed a vote of thanks to Prof. Forbes for his Paper. When thinking of the condition of electric lighting in this country one felt a great amount of depression, and it was only when listening to such Papers as that of Prof. Forbes, where they heard of the progress made in other places, that one felt that there was a possibility and a probability of that depression being removed. There was every prospect of it being removed in London, as we were now on the verge of a boom in electric lighting. The Commissioners of Sewers had now decided to issue at once specifications, to which tenders would be invited, to light up the whole of the City. It was hoped that tenders would be received from those who were competent to carry them out, and that before the end of the year Fleet-street, Ludgate-hill, and Cheapside would surpass the Unter den Linden. He agreed with Mr. Crompton that for fitting up private houses the proper candle-power to use was from eight to ten candles. Of course it would be absurd to light up the room they were now in with 8-candle lamps. Two things were wanted. They wanted to speak of the lamps not of so many candle-power, but of so many watts. The standard lamp that was being introduced, the standard lamp in his own immediate practice, was a lamp of fifty watts. Throughout the Post Office they commenced with 16-candle lamps; but they found that 10-candle lamps gave all the light they wanted. The second thing required was not the power of the lamp but the distribution of the light over the area. When they knew the amount of light they wanted on the surface of the work they were doing it was an easy matter to calculate whether the lamps should be of 30, 50, or 100 watts, because that simply depended on the position of the lamp and the distribution of the light upon the area below. He should like very much to join Prof. Ayrton in attacking Prof. Forbes upon the question of measurement, but it would be quite unfair to do so now, as Prof. Forbes would have no reply. They had been told that Mrs. Ayrton had been experimenting on a meter actuated by the principle of

Digitized by Google

evaporation, water being used. Prof. Forbes, on the other hand, had introduced to them a very beautiful meter, dependent upon the evaporation of alcohol. The greatest benefactor in this instance would be the man, if he ultimately succeeded in producing a field where all the alcohol of the universe could be evaporated (laughter).

The vote of thanks was then carried by the meeting, and the proceedings terminated.

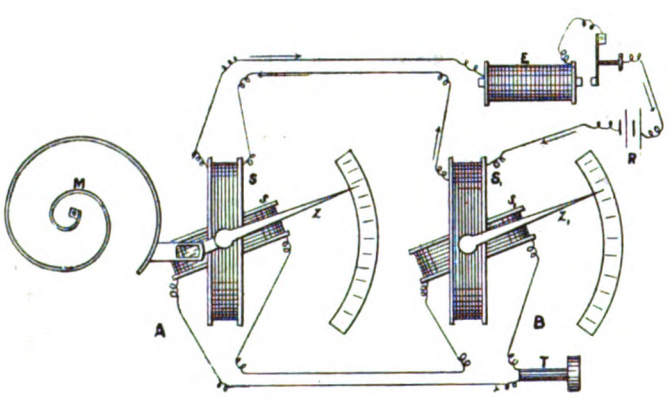
The illustration below represents the latest type of Forbes meter, which may be compared with the earlier type illustrated in our issue of February 8th. The following are the chief points of difference between the new and old types :—The wheel work is much lighter in the newtype; the conductor is of different form and of lower resistance, the spiral of wire being replaced by a number of cross



wires placed in parallel between two concentric rings. The point on which the mill wheel rests is more slightly rounded.

THE MŒNNICH INDICATOR.

We give below a diagramatic representation of a novel type of indicating apparatus, which has been devised by M. Paul Mœnnich, of the University of Rostock. M is the instrument whose move-



ments it is desired to reproduce at a distance. Some sort of flexible material, intended to undergo alterations in length, having some relation to the particular phenomenon (temperature, for instance), which is to be measured, is fixed to the coil s, and varies its position with regard to the external coil S. A similar arrangement exists at B, the point of observation. The coil s_1, which is wound in the reverse way to s, is in the same circuit as the telephone T and the coil s. The coil S_1 is connected to a battery, R, a trembler, E, and the coil S. Suppose the coil s to be in a certain position, the pointer z being at the corresponding division on the scale. If an intermittent current is sent along the line induction will cause noises in the telephone so long as the coil s_1 is not in the same position with regard to the coil S_1 as the coil s is with regard to the coil S. When silence is obtained s and s_1 are therefore in the same relative positions, and the position of the pointer z_1 will correspond to that of z. It is obvious that the principle is susceptible of a variety of applications.

THE ARON METER: LATEST TYPE.

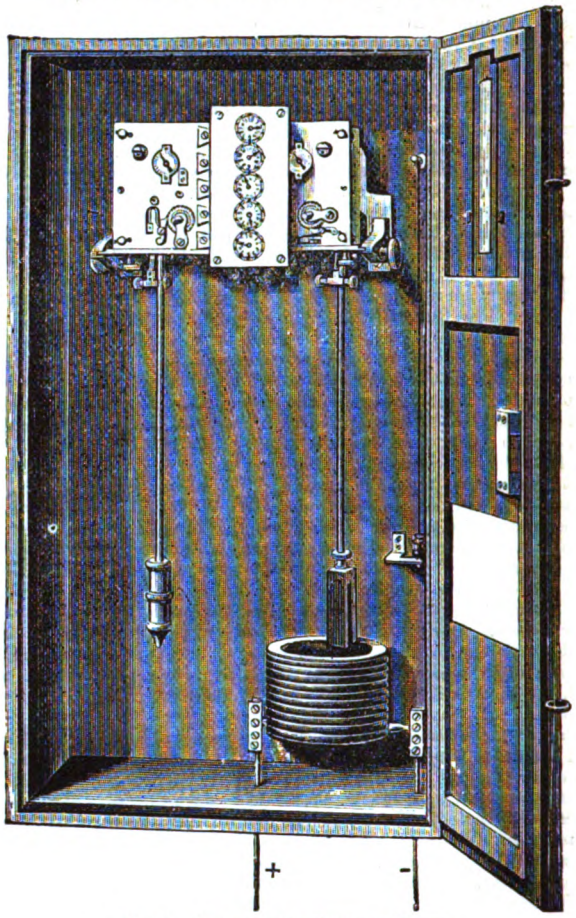


FIG. 1.—ARON DIRECT CURRENT METER.

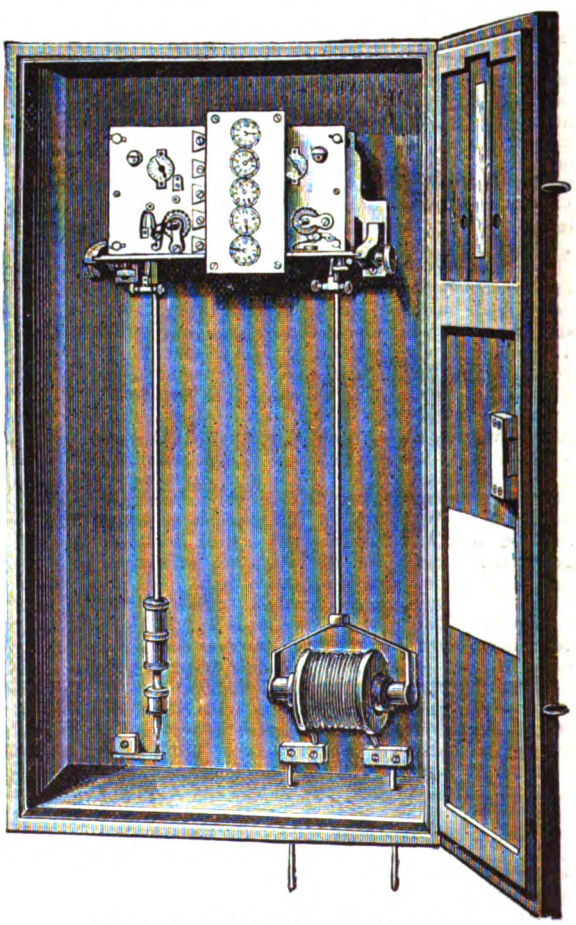

FIG. 2.—ARON ALTERNATE CURRENT METER

We illustrate herewith the latest types of the Aron meter for continuous currents (Fig. 1), and for alternating currents (Fig. 2).

Digitized by Google

The following description will give an idea of the construction of the instruments:—In the direct-current meter (Fig. 1) two pendulums control two distinct clockwork gears. One of these is a standard, oscillating at a regular speed. The other has a permanent magnet instead of a weight, and is variable in speed. The variation is obtained by passing the entire supply of current to be recorded through a solenoid of thick wire placed underneath the magnet. The magnetic influence of this solenoid has an accelerating effect on the pendulum in direct proportion to the current passed through. The difference of speed between the standard and magnetic pendulum is given in direct ampere hours by differential speed counting gearing, on a similar principle as a gas meter index. The slightest alteration in the current passed through is thus recorded.

In the alternate-current type the principle is the same. One pendulum carries an ordinary metal weight, whilst the other one ends in the shape of a fork, which carries a coil of thin wire. This small coil is connected up in shunt, and moves freely inside a larger one, wound with thick wire, through which passes the main current. The effect of these two coils acting upon each other causes an alteration of the speed of the measuring pendulum, which is proportionate to the product of the existing E.M.F. and the strength of current. The clock went for six weeks without winding up.

The loss of E.M.F. with a current of, say, 100 amperes does not exceed 0·05 volt, owing to the small resistance in the measuring coil.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *February 2nd*, 1889.

You have already been informed by cable and letter of the recent important decision of the United States Supreme Court in the Bate Refrigerator Company's case with regard to the effect of foreign patents on the term of United States patents. This decision, as has already been stated, has very direct bearing on a number of electrical patents, particularly those of Mr. Edison, as mentioned in my last letter. Under the circumstances, as might be supposed, the value of Edison Stock has risen very materially, and those who are interested in the Edison Company are quite elated and sanguine as to the final outcome of the suits when the patents are pushed to trial. The Edison lawyers in this city have not lost any time in availing themselves of the decision, but are already seeking to secure some of the fruits of it. They obtained an order in the United States Circuit Court this week, calling upon the United States and other Companies against whom action for infringement has been brought to defend themselves, and as the order is returnable this week it looks as though the various infringement suits would all be prosecuted actively. Now that the full text of the decision has been published by the electrical papers, it is seen that although the ruling is a very important one in many respects, it is not so altogether conclusive over the whole disputed field as might at first have been supposed. The Court, for instance, did not make any decision as to the exact meaning in the statute of the obscure words "first patented, or caused to be patented, in a foreign country." And it would appear from the phraseology of the decision as it stands, that if foreign patents had been granted for a short term and no extension had been obtained, the United States patent subsequently granted while the short term continued would certainly lapse at the expiration of that term. In fact, it would seem that the Supreme Court holds that the lifetime of the United States patent is affected solely by the expiration of the foreign patent, and that the term for which the foreign patent is granted upon its face has little or nothing to do with the matter. Here, however, a question might arise as to whether expiration would mean the end of the full term for which the patent was granted, or its sudden decease for want of sustenance in the shape of continued fees.

The interest that is being taken in electric railway work in all parts of the country grows every day, and it looks now as though the present year would see a general boom in this department. Two or three years ago the capitalists who were willing to interest themselves in electric railway schemes, and invested their money in them, were, as is usually the case, men of somewhat sanguine temperament and more enterprising than the rest of the community. They were often laughed at for their pains, and have been freely entertained with predictions of failure and disaster almost down to the present time; but with the increase in the number of roads, and the improvement in their methods of operation, there has been a most significant change of front on the part of those who were disposed to condemn such undertakings as hazardous and risky. Probably no more significant evidence of the new attitude towards the young industry could be found than that which is conveyed in the announcement that the Pennsylvania Railroad is about to put in an electric railroad at Atlantic City, N.J. This company is one of the largest and wealthiest of our railway corporations, and with the aid of a splendid engineering corps it conducts its system in a manner which often reminds tourists from the old country of the solidity and smoothness with which they are so familiar. It has recently been looking into the question of street railway operation, and has had an expert committee investigating the relative merits of the different systems of electricity, cables, &c. The inquiry lasted nearly six months, during which time the committee visited all the larger cable and electric roads in the country, and the outcome is that a contract for the building of the road at Atlantic City has been awarded to the Sprague Company, which is to put in an overhead system there. The effect of such an action as this upon the community at large must be great, for the Pennsylvania has never been known to approve thus heartily of a thing that was not very good, and it is always sure to find many followers. I should not be surprised a short time hence to find the Pennsylvania Railway Company employing electricity to operate some of its shorter branch lines on which it is now using the old steam locomotive.

In connection with the above remarks on electric railways, it is timely to note the great street tramway strike which has been agitating New York and Brooklyn for the last fortnight. The strike began in Brooklyn last week, and then spread to New York on Monday, since which time street tramcar service in this city has been practically suspended, while Brooklyn has been not much better off. If it were not for the elevated roads I do not know how business could be carried on, as they are virtually the only means of passenger transportation at the present time, except hacks, the hire of which, as many of your visitors to New York know, costs as much as the purchase of freehold estate in England. The magnitude of the strike may be judged from the fact that in this city alone over 6,000 men connected with the roads have left their work. In the meantime, of course, although no cars have been running, all the horses have to be fed, and their keep and care represents a very large item of cost. I do not know just how many horses there are engaged in street tramcar work in this city, but the number must reach several thousands. On the Broadway road alone there are close upon 2,000, or 12 to every car in service. One of the Brooklyn roads has no fewer than 3,000. Of course, if the roads in question were operated by cable or by electricity, the plant could be at once shut down, and there would be no expense or outlay on the score of power. But here, again, the advantage tends towards the side of electricity, for while the power required to run just one or two cars with electric motors would be strictly proportionate to the work done, in the case of a cable system, whether it were one car or a dozen, the road would have to carry its huge and heavy cable all around its system. It need not be wondered that under such circumstances the managers of our street railroads are inclined to look very thoroughly into the question of adopting electricity for motive power purposes.

An interesting new departure has been made during the present week in this city by the C. and C. Motor Company. They have moved into a magnificent new factory in Greenwich-street, where they will make their well-known motors, of which several thousands are now in use in this country, and of which I believe also a number have already been sold in England. The peculiarity of this building is that, although it is intended for manufacturing purposes throughout, no provision other than electrical has been made for the distribution of power. It is the intention to place motors on every floor according to the power that may be required there at any time. The generating plant is in the

Digitized by Google

basement, where a huge 50,000 Watt-Edison dynamo is running all the time, furnishing current to every floor upon which it may be required. The whole of the extensive machinery of the company itself is thus run by their own motors, taking current from this generator, and on the floors which are leased for miscellaneous purposes the power is supplied in the same way. Thus, for instance, a manufacturer on coming into the building is asked how much power he wants and where he wants it, and he is immediately given that power in one motor or half a dozen in the exact position where it is most advantageous for him to apply it. It will readily be seen that such a system presents enormous advantages over the old method of supplying power by steam with its big belts and long lines of shafting, or by the even more expensive and annoying method of having a number of engines or steam plants all over the building. The building is well laid out, and wires are neatly run to each floor, and the whole works like a charm. It is also the intention of the company to distribute power from its generating plant to manufacturers in the neighbourhood. Altogether, this departure is a most interesting one, and it is attracting a great deal of attention.

The approaching convention of the National Electric Light Association at Chicago promises to be very large. It will be remembered that the association took its birth at Chicago three or four years ago in a modest way. In the interim it has visited for its semi-annual meeting several of our large cities, including New York, Boston, Philadelphia, Baltimore, Detroit and Pittsburg, and now goes back to Chicago with a large and vigorous membership to make a far greater impression on the West than it did when it began its work. There can be no doubt as to the good effect of these gatherings, though perhaps they come a little bit too often so far as the participants are concerned. Local interest and curiosity is aroused by the gatherings, the exhibition always attracting a great many spectators, and I believe in every instance the convention has been followed by local development of electric lighting and power. This month at Chicago the convention will be in the Exhibition building, and a very large and fine exhibit is to be made of electric lights, motors, and railway systems. It is believed that this will be very attractive to the people of Chicago, and hence arrangements have been made for the distribution of no fewer than 100,000 admission tickets. The good effect of this display on Chicago and the section of country around about it can easily be imagined, and there is every prospect that the convention will be fully as useful as any of its predecessors.

CORRESPONDENCE.

THE EFFECT OF CURRENTS UPON CONDUCTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I was much interested in the experiments of M. Firmin Larrogue, described in a leaderette in *The Electrician* for February 1st, but was somewhat surprised to find that his results seem to show that alternating currents produce a greater change in the molecular structure of a copper wire than do continuous ones.

About two years ago I was giving this matter some thought, and on making various inquiries among dynamo makers (one of them, at least, had a large experience) I found that they were of the decided opinion that the wire on the armature did not harden nearly so much, nor so quickly, as the wire on the field-magnets. This is with continuous-current machines. No tests have been made, and this is merely a statement of opinion. Of course the continual heating and cooling would alone tend to harden the wire; but this hardening would be greater in the armature, as it is usually at a higher temperature than the field-magnets.

About the same time the Grosvenor Gallery Company were good enough to let me have a sample of wire which had had an alternating current running through it for a very long time. I could not, however, find in it any trace of hardness other than that due to the slight coating of "rust" always found on wire, whether it has been carrying a current or not, after it has been for any length of time in an ordinary installation. After passing a piece of it through an annealing process it was apparently no softer than the original wire, which proved that there was in this case no "strain" in the molecular structure. These statements do not agree with the results obtained by M. Firmin Larrogue. In the case of the induction coil wire he mentions it would be interesting to know whether the effect might have been due to its having been boiled in impure paraffin wax or to its having been kept in the damp. The account of the wire taken from a lighthouse loses much of its interest owing to its not being stated whether it had been conveying a continuous or alternating current.

Perhaps the following will interest, as bearing on this subject:—Dr. Mouckman, for some experiments he was doing here, required a platinum wire in a perfectly annealed condition, which was tested for thermo-electrically (a very sensitive test); of course the method which naturally suggested itself was heating by means of a current, but he found it impossible to thoroughly anneal the wire thus, and had to resort to external heating, when there was no difficulty in getting the required result. He also found that when *once* the wire was annealed that heating it up by the current produced no strain. From this may fairly be argued that the current has a tendency to produce a strain in this sense, but that for such to become permanent, time is probably an all-important factor.

It would be interesting to know if the current has any effect on perfectly *pure* wires. It was from this point of view that the matter was interesting to me, as I was somewhat doubtful as to whether we should make our standard resistance coils from wires of alloys.

Some of your readers who have German-silver resistances in use on installation work (continuous and alternating current) may be able to say whether they harden or not. The coils should, however, not have been habitually heated.—Yours, &c.,

A. T. BARTLETT.

Cambridge, February 9th, 1889.

THE REGULATION OF DYNAMOS BY MEANS OF A THIRD BRUSH.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the editorial columns of your journal, under date of December 21, mention was made of the recent Paper by Mr. Edward Caldwell upon "Third Brush Regulation of Dynamos."*

Since the topic is one which cannot fail to interest students of the dynamo, I may perhaps be permitted to say a word with reference to the machine with which his investigation was made. The dynamo in question is a small machine constructed for experimental purposes in this laboratory; but although it is not modelled after any existing commercial type, it possesses no peculiar features to which the results obtained by Mr. Caldwell can be ascribed.

When used as an ordinary two-brush series-wound machine, its characteristic, as given in his Paper, is a curve of the form which a properly constructed dynamo of that type should give The electrical efficiency, also, will compare favourably with that of large machines of our usual commercial types. Readers of Mr. Caldwell's Paper will, I am sure, agree with me in saying that the dynamo in question, under his management, showed unusual freedom from those perplexing idiosyncrasies with which the experimenter is apt to meet when he attempts to subject a machine to new and unusual conditions. In the systematic way in which, in the second half of the Paper, the "series" characteristic is modified, step by step, until the condition of complete regulation is reached and finally passed by, they will moreover recognise, I think, the development of a method which is applicable to *any* series dynamo.

The point to which I desire to call attention especially, however, refers to the position of the diameter of commutation during Mr. Caldwell's experiments, and the influence of changes of the same upon the direction of the current in the third brush line. The possibility of such an influence was recognised at an early stage of the investigation, and determinations

**The Electrician*, Vol. XXII., Nos. 554, 555 (reprinted from the New York *Electrical Engineer* for December, 1888).

Digitized by Google

of the distribution of potentials within the armature were made by explorations of the field under various conditions.

In the original thesis* in which these experiments were described, the curves resulting from these explorations are given, together with the readings upon which they are based. In view of the very simple explanation of the action of the third brush developed in the course of the subsequent measurements, this portion of the work was, unfortunately perhaps, omitted from the abstract published in the *Electrical Engineer* of New York.

I present, in the accompanying Diagram 1, one of these sets of curves, selecting an extreme case which will bring out the reaction of the armature at its worst, and the influence of the third brush circuit upon the strength of field and upon the distribution of potentials, when nearly one-third of the entire current in the armature was flowing through the third brush. The curves in question represent the result of a single set of galvanometer readings around the armature, subject to the irregularities due to slight changes of speed and to the various other minor disturbances incident to such measurements. Their trustworthiness in every important feature has, however, been established by repetition of the observations.

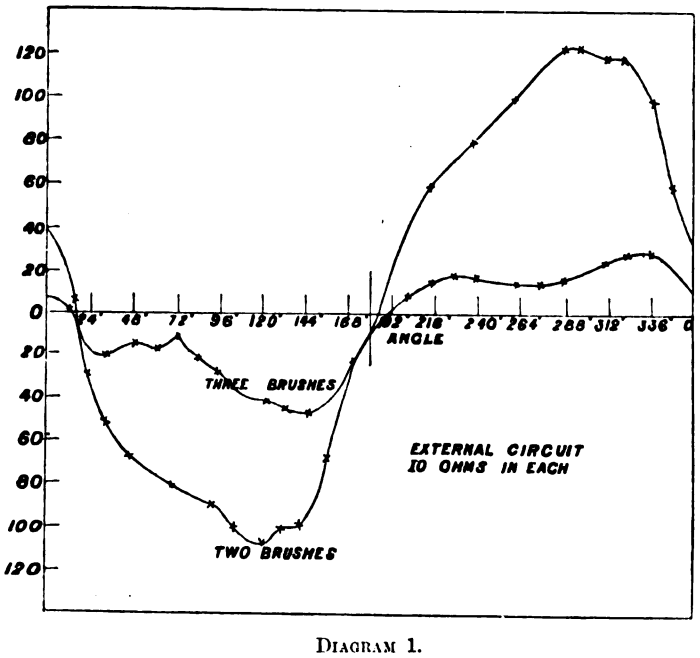

DIAGRAM 1.

In this case the reduction of the current is effected, as Mr. Caldwell has pointed out, by diverting the requisite proportion of current from the field coils and allowing it to pass through the third brush circuit. The current thus diverted amounted in the case in question to 0·90 ampere. Curve *b* Plate A shows the distribution of potentials under these conditions. The field is much diminished in intensity and the curve is modified, but the diameter of commutation has not changed appreciably, and the positive and negative brushes, with a lead of 12 degrees, need no readjustment.

The dynamo was first driven as a two-brush machine, giving 4·3 amperes through 10 ohms external resistance. This corresponds to a point well out upon the "series" characteristic, as will be seen by reference to Plate A of Mr. Caldwell's Paper. The brushes were given a lead of 12 degrees, which position corresponds very closely with the neutral points of the curve of induction (*see* curve *a*). The armature reaction is well marked but not excessive, and the distribution of potentials, to say the least, is fairly symmetrical for so small a machine. The third brush was then brought into place upon the commutator at a distance of 36 degrees beyond the positive brush, and the machine was adjusted for constant current at 1·70 amperes. The external resistance, as before, was 10 ohms.

* "Dynamo Regulation for Constant Current and Constant Electromotive Force, by Means of a Third Brush: a Thesis in Electrical Engine ering." By Edward Caldwell, M.S. in the library of Cornell University, 1888.

In another set of curves, which need not be reproduced here, the external resistance is 80 ohms. The position of all the brushes is the same as before. The function of the third brush in this case is, however, to strengthen the current through the field coils, and the adjustment is such as to send the current through the third brush circuit in the opposite direction. The curves show a much stronger field with three brushes than with two; the symmetry of distribution is still well preserved, and the shifting of the diameter of commutation is scarcely appreciable.

The principle upon which the experiments described in the second part of the Paper are based is extremely simple. Let a third brush be placed anywhere upon the commutator of a series-wound machine. A point in the external circuit can always be found, the potential of which will be the same as that of the third brush. If the brush be connected with this point no current will flow between them. Any change in the resistance of the external circuit will destroy the equilibrium however, and current will then flow through the third brush circuit. It is evident, moreover, that the direction of this current will always be such as to tend to the maintenance of constant potential at the terminals of the machine. Mr. Caldwell has pointed this out very clearly, and he has shown by experiment that very complete regulation for constant potential may thus be obtained. I have endeavoured to show, very briefly, that the dynamo with which his results were obtained does not differ from other properly-constructed machines of its class to an extent which would lead us to question the applicability of that method of regulation to all series-wound dynamos.—Yours, &c.,

EDWARD L. NICHOLS.

LIGHTNING CONDUCTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Owing to a press of work I have been unable to give, hitherto, more than a glance at the various letters and articles on the above subject originating with the Presidential Address of Mr. Preece before Section A of the British Association meeting at Bath last September, and which have been since continued in *The Electrician*. Considering the great importance of the subject, and the very wide field for ascertaining the precise nature of the electrical and atmospherical phenomena constituting lightning discharges, and the ample means which electricians, especially abroad, have of thoroughly studying them and taking exhaustive observations, it is indeed surprising that the field of discussion should have been so entirely left to Prof. Lodge, whose very clever and hitherto accurate experiments, however, must have met with the unanimous approval of all scientists, whether theoretical or simply practical.

It is to be regretted that any dissension whatever should have risen between the two camps thus constituted, because it must be admitted that the boastful axiom of "one grain of practice being worth a pound of theory" has been pretty well thrashed out of countenance, at least as far as electricity is concerned; and a careful examination of the whole discussion tends towards the fact of a misunderstanding having been produced by a certain quantum of acrimonious verbosity rather than a fixed antagonism of the question at issue. Mr. Preece, as an eminent practical electrician, has no doubt much reason to justify his depreciation of certain *soi-disant* theorists and mathematicians in embryo who have done so much to plague the life of a purely practical man; yet he would be the last one, I am sure, to undervalue the absolute necessity for proving the accuracy of any admitted practical fact by working it out in theory, and Prof. Lodge's valuable experiments are apparently tending not only to substantiate his own theories, but to prove that the practical man's lightning conductor is equally affected, although, until proper attention had been drawn to it, these phenomena were not observed. Hence it is that by a regular and general system of accurately recorded future observations we may hope to eventually arrive at a fairly correct solution of the disputed

Digitized by Google

problem; and with the view of rendering assistance in this research, I propose to describe certain instances of lightning discharges which have, at different intervals, come under my direct personal notice.

The Eastern Telegraph Company's quarters at this station face the sea, and are separated from it by a mole some sixty feet away from it. At one corner of this mole stands a wooden flagstaff forty-five feet high, kept in position by a base socket hole one foot deep, a stone wall two feet cube, and four rope stays connected to an iron ring half way up the pole, and to the surrounding rocks below. This was erected in 1882, and as there was no record of the original flagstaff (which during the English occupation of the Ionian Islands, and under precisely the same conditions, had always stood there) having ever been struck by lightning, a guard was not considered necessary. Shortly afterwards, however, this flagstaff was destroyed by lightning during a storm of exceptional violence. It was purely a side stroke, the lightning falling on to the iron ring, smashing off the upper part, otherwise uninjured, and tearing away, in a groove-like spiral form, the lower part as far as the wall, which was split asunder; the rest of the pole, from the top of the wall to the base, was untouched, so that the discharge took an alternative route, and "splashed" into the sea after striking the wall. This was accurately proven at the time.

A similar pole was subsequently erected to replace the destroyed one, with a length of ordinary thick iron telegraph wire run up it and fastened into it by staples showing slightly above the top, the other end being in the sea. Many thunderstorms of varying intensity have occurred since then in the immediate vicinity of this house, but the pole has never suffered from them in the slightest possible manner, and it is to be assumed that the iron wire permits the entire discharge to pass along it, and owing to the small surface of the pole there is really little or no reason for it to errate by any alternative path, and thus the iron wire (its conductivity being, for this purpose, as good as copper, and, of course, immensely better than the wood) constitutes in this case a sufficient protection; and although the resistance of the "earth" is in ohms and not in microhms—about which a great amount of futile correspondence took place some time back—I do not hesitate to say that the pole is quite as safe as if it had one of the so-called orthodox lightning guards fixed upon it.

A still more illustrative example of this peculiar phenomenon occurred in Zante during a thunderstorm in February, 1886. A boatman was conveying a passenger to a steamer in port, and it was raining heavily, with occasional lightning discharges; the boatman was standing up facing the bows of his boat whilst rowing, the unfortunate passenger being seated in the stern sheets under a large cotton umbrella with a spiked metal ferrule to it. In order to reach the steamer the boat had to pass within a short distance of the dredger, a huge iron affair, with its lofty iron derrick wheels, chains and buckets all in position. When close off this dredger a lightning discharge, which, according to all theoretical and practical laws should have passed to earth *entirely* by the dredger alone, did not, however, do so, but part of it went by the alternative path constituted by the umbrella point, thence along or through the man's body to his knife stuck in his waistband behind, killing him instantaneously, singeing his clothes, and discharged itself through a nail in the side of the boat, which was there splintered and scorched. The boatman was stunned, but otherwise uninjured, and his version of the occurrence and an inspection of the body and the boat was taken by me within a few minutes of its happening.

About the same time I was asked by the surveyors to examine an English brig which had put into the port of Zante leaking from the effects—as reported by the captain and crew—of having been struck by lightning. The discharge must have been, from their description, one of great severity, and the inspection furnished undoubted proofs of its having been struck from the side. The mainmast was damaged from the lower yard-arm metal connections downwards, from whence a chain was hanging, and had been, intentionally or otherwise, twisted round the bilge pump right alongside of the mast. The weather vane and metal above the yard-arm appeared untouched. The leakage was caused by the discharge going down the chain and the pump, and then through the ship's bottom or side into the sea, but it had evidently "splashed" about considerably on reaching the deck, as everything metallic—notably, bolts and nails—seemed to have been affected by it, although, strange to relate, the captain, who was in the immediate vicinity of the mainmast, and who was temporarily blinded by the vividness of the flashes, was otherwise uninjured. It had not rained, however, previously, although the discharge was immediately followed by torrents of rain.

A final instance occurred last year. A one-storied house, situated on some rising ground behind the town of Zante, was struck by lightning, and a young man sleeping on the ground floor was killed. The discharge struck the external iron shutter fastener of an upper window facing the west, entering the room and leaving it by the inner and outer iron fastenings of another window on the same floor facing the north, from whence it went to earth by the outer wall. In its path to earth it met with the large iron-barred and closed window of the room in which the lad killed was sleeping upon a straw mattress on a dampish stone floor. A blue mark on his face and the discoloured features plainly showed where the derived discharge had struck him, and a rent in the bottom of the wall and the floor in the *opposite* corner where it had entered the earth.

These four cases, which I trust have been described with sufficient clearness, offer indisputable proof that lightning discharges follow precisely the laws relating to electricity and derived circuits, except that the ratio of discharge, owing to the intensely higher potential, and the electric inertia of the immensely larger surface of the building, compared with its protector, render the alternative path almost a necessity in certain instances; and it therefore follows that both theoretically and practically any building whatever having iron or copper bands of a sufficient breadth bound across the top and sides in four or more different directions, and connected to the—not necessarily "perfect"—earth would be far better protected than the same building having one single large copper conductor with a multiplicity of points and an earth of absolutely no resistance; and although there is not a shadow of doubt that Mr. Preece's observations about unscientifically constructed and uninspected lightning conductors adding to the danger unprotected buildings run are truisms, it certainly does not follow that they would enjoy absolute immunity from danger if they were alone protected by his orthodox lightning guard. If it were an absolute law that lightning discharges have an affinity for pointed objects only, it is an astonishing fact that ships are not more frequently struck than they are, considering how constantly they are subject to their influence, and how small is the proportion furnished with lightning protectors, and that every craft all over the world has some insulated metal connection or another aloft. May we not rather assume that the electric inertia of the *mass* carries off the entire discharge, leaving the points as the very feeble alternative path?

In England and America we may be pretty certain that lightning conductors are fairly well constructed and periodically inspected; abroad this is the exception, not the rule. Yet all the world over do we not find that, considering the immense disproportion in the number of protected buildings compared with unprotected ones, the cases of damage are as frequent, if not more so, in the former than in the latter? In many parts of Europe, in Italy, and all over the Levant especially, it is the rule to have high churches and other towers surmounted by a long metal weather vane or a huge iron cross, and yet instances of their being struck seldom or never occur; on the other hand, I remember that when the powder magazine at Scutari, in Albania, was struck some years ago, it transpired on the inquiry that the whole of the lightning conductors, *except the points*, had been removed, the wires to earth being considered unnecessary.

In 1883, when in Corfu, I was asked by the Prefect to examine the lightning guards on the powder magazine at the castle, and I found them entirely disconnected from the earth, and they had evidently been so for many years; whilst a final instance we have in Zante, where at the signalling station up at the castle—700 feet high—they have a hollow iron telescopic flagstaff raised on the top of a wooden pile driven into it and into

Digitized by Google

the ground in order to increase its height, and a stone wall built up flush with the base plate; yet up to the present it has never been damaged.

In conclusion, I would state that on one occasion I happened to be in a wooden-lined iron cable house during a terrific storm, and with the lightning playing all around it. The sense of security, when inside, is perfect, and as Sir Wm. Thomson says, the safety *is* absolute, whether that hut be built on the rock or on the so-called "perfect earth," provided, however, it and you are quite dry; but I confess that I would as soon think of holding a perfectly constructed lightning conductor during a storm as be wet through and on a wet floor inside an iron hut.—Yours, &c.,

W. G. FORSTER,
Manager and Electrician, Eastern Telegraph Company.

Zante, January 17, 1889.

GLOBULAR LIGHTNING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Globular lightning is the electricians' sea-serpent. It has several times been scotched, and always appears in the "silly season," when Parliament is not sitting and electricians have nothing better to do than utter platitudes about insulation resistance. While not denying the great interest attaching to this most mysterious of electrical phenomena, I must enter a protest against the appearance of more than one globular story in one number of *The Electrician*. Last week there were actually two such stories; it is too much. On page 390 is a note to the effect that M. de Paulpiquet had half a lightning ball fixed on his horse's chest. I firmly believe in M. de Paulpiquet; his account bears internal evidence of its truth, for he tells us the horse died from the effects. Of course it did—what horse could survive lightning on the chest?

Some years ago a description appeared in *Nature*, I think, of a fiery globe which, after chasing a French gentleman for several minutes, exploded, leaving a quantity of mercury on the floor. That story also must be true, otherwise one cannot account for the mercury. In short, I believe all such stories when they come from France; but how can Mr. Fahrig (page 413) expect us, just after swallowing the horse affair, to believe his somewhat excited description of the several meteorological phenomena witnessed by him? Item: "A fireball *two* metres in diameter." One cannot but admire the intrepidity which enabled Mr. Fahrig to risk certain death in order to make an exact measurement of the diameter! Item: Bluish, fiery light. It would be likely to be fiery seeing where it came from. Item: An explosion lasting *two* seconds. Item: A snowstorm, which in *two minutes* deposited 1½in. (oh, why not 2in. !) of snow on the ground.

Now, sir, last Sunday I was in the country, and for over two *hours* it snowed hard without stopping. I thought of Mr. Fahrig, and measured the snow in three or four places; average depth about 1½in. However, I have it from two quite independent sources that a brilliant flash of lightning, followed by sharp thunder, was observed *during* a snowstorm at Stamford Hill, on February 2nd, so that there may be a place in history for Mr. Fahrig's fireball if he will kindly reduce its diameter to circular measure, and state the elements of its orbit somewhat more precisely. We will make allowances about the snow. I almost saw a fireball myself once; it was terribly exciting.—Yours, &c.,

SYDNEY EVERSHED.

CONSTANT-CURRENT REGULATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you kindly permit us a line on the so-called Edmunds method of maintaining constant currents, and as to the information lately received that Marcel Deprez was the first to explain the theoretical principle on which this regulation for constant-current is based.

This principle was first applied by our engineer, Mr. Joseph Kirkham, in the year 1884, with results equally satisfactory as those recorded by your correspondent in the February number of *The Electrician*, page 379.—Yours, &c.,

JOHN SMITH AND CO.

Moscow, 28th Jan.—9th Feb., 1889.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

COMPANIES' MEETINGS & REPORTS.

The India-Rubber, Gutta-Percha and Telegraph Works Company (Limited).

The twenty-fifth ordinary general meeting of the shareholders was held at the City Terminus Hotel, Cannon-street, on Thursday, Mr. S. W. Silver, the Chairman of the Company, presiding.

Mr. WILLIAM J. TYLER (the Secretary) read the notice convening the meeting. The report and accounts were taken as read.

The CHAIRMAN said: I think, gentlemen, the report embodies much or most of what I have to say. Nevertheless, I may in a general way refer to the circumstances under which we are met to-day, as compared with twelve months since. The general trade of the country has increased, and I am thankful to say that the operations of this undertaking have expanded fully in proportion. We have passed through a year of trade in which our general sales have equalled and exceeded those of any previous year. Here, I may venture to say, we have evidence of the prepared state of our works for any demand that may be made upon them, which I think we may attribute that to the prudent judgment and the energy and ability of the members of the staff. In making that remark I certainly cannot pass over my friend on my right (the Managing Director), who gives to this concern, I may say, the best hours of his life. So far as regards that side of the question. There is another side of equal importance to us, largely interested as we are, and that is as to the profit. Owing to the keen competition we meet with in beaten tracks I am not in a position to say that the profit is at all in accordance with the amount of sales; nor must we look for it, unless we go into new fields and seek out new outlets, such as those appliances connected with electricity. There are many and varied openings in connection with electric lighting, and so on; and I am glad to tell you that our works, as far as that branch is concerned, are well employed. We have as the result of the year's operations a net profit of £57,157. That amount, with the sum brought over from 1887, shows a total of £66,687, out of which we recommend a payment of 10s. per share as dividend, in addition to that paid last July, which will make up upon the year 10 per cent., and enable us to carry over £25,000 to next year's account. Now, that is a very useful sum to us. Our stock at times has to be supplemented so as to take advantage of the offers that are made to us of raw material. We come now to the submarine branch. We have done little there as compared with our resources in staff and plant; but I am glad to tell you that we are now very much better employed, and are likely to be for months to come, and our vessels will then have something to do. No profit, however, has been taken on account of these new cables. As regards all the other branches, we are in a generally efficient state at Silvertown, and the same may be said of Persan-Beaumont, which shows an improvement on last year in its operations. With these remarks I think it only remains for me to move:—

"*That the report and accounts now presented be received and adopted, and that a dividend of 5 per cent., or 10s. per share, income-tax free, payable on and after the 15th inst., be now declared.*"

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.
The best for overhead Telephone and Telegraph Lines,
AND ALL ELECTRICAL PURPOSES.
Hard Drawn High Conductivity Copper Wire.
ROLLED AND DRAWN
PHOSPHOR BRONZE.
PHOSPHOR BRONZE
BEARINGS, BUSHES,
AND OTHER PARTS OF
ELECTRICAL MACHINERY.
SOLE PROPRIETORS of the British, Indian and Colonial Patents,
THE PHOSPHOR BRONZE COMPANY (Limited),
87, Sumner Street, Southwark, London, S.E.
WIRE AND SHEET MILLS: BAGOT STREET, BIRMINGHAM.

Mr. ABRAHAM SCOTT seconded the motion.

The CHAIRMAN: We shall be glad to hear any remarks or to answer any questions.

Mr. LAMONT: May I ask whether the steamers have been earning anything during the past year? You say they have had very little to do.

Mr. COCHRAN: Before you answer that question Mr. Chairman, I should like to make a remark or two. I think I shall be in the recollection of the shareholders who were at the meeting in 1886, that serious objection was taken to one of the conditions you asked the shareholders to authorise, and that was that no objection could be taken to the Directors' remuneration unless proposals were submitted to the Board seven days before the general meeting. To meet that difficulty, and in order that there might be no split, it was decidedly the feeling of the meeting, and an undertaking was entered into by your predecessors, that ample notice should be given of all future meetings of the Company, and that the report should be issued in sufficient time to enable any shareholder who might wish to take objection to these remunerations to lodge a notice. Now, I have to draw attention to the fact that this arrangement, no doubt through an oversight, has been overlooked, for this report was issued exactly a week prior to the meeting. I think this ought certainly to have been obviated, and I think the time has come for us to consider whether the remuneration which we are paying to our Directors is a reasonable one. The fees of the Directors are charged in the accounts on this occasion £3,728, which, distributed among five gentlemen, comes to just about £750 each. I submit, gentlemen, that while we ought to pay the gentlemen who are managing our business a fair and reasonable remuneration, with the ample and notoriously efficient staff and the able management of this Company, we are paying our Directors decidedly too much. It is very nearly 10 per cent. upon the whole amount that the Directors are distributing among the shareholders. I know I am out of order, because I cannot move a resolution to-day owing to the circumstance I have referred to; but I call attention to the matter for two reasons. I think the Directors would act wisely in meeting the shareholders and agreeing that this excessive amount should be reduced. There were reasons why such a large amount was paid in previous years, but those considerations I feel no longer hold now, and I think the shareholders ought to have some revision of this scale. We have, we all know, an admirable Managing Director, to whom we have all looked for the wise conduct and management of this concern, and we also clearly recognise that our Directors ought not to be paid shabbily; but I submit that the time has come when this arrangement ought to be revised and a fresh scale submitted.

A SHAREHOLDER: I received lately from the Gas Light and Coke Company a list of subscriptions to the North Woolwich Gardens, and I see, gentlemen, that you have subscribed £500 out of the funds of the Company, which I think was hardly in place, seeing the condition we are in.

Mr. TOYNTON: I notice that the gross profit and the interest and profit on debentures and shares in other companies are lumped together in one sum. In previous years they have been divided. May I ask whether there is any objection to the separation of them?

Mr. EVENNETT: I should like to refer to the item of debentures and shares in other companies. Will you explain the difference between the amounts in the last two accounts?

The CHAIRMAN: As you suggest, Mr. Lamont, the steamers have done comparatively little work during the past year. Then, in reply to Mr. Cochran, I may say that a shareholder can give notice of any alteration. As regards the shortening of the time on the present occasion, we had the interests of the shareholders in view in holding the meeting one week earlier than we might otherwise have done. The delay in holding the meeting was complained of last year. As regards the subscription to the North Woolwich Gardens, that seems to us to have a very ready answer. It is in the interests of our workpeople. I am afraid, sir, you do not know the pest that garden was to the neighbourhood. If you knew the neighbourhood as we all do here, you would be thankful to promote the removal of it and the application of the space to a far higher and better purpose. As you are aware, we have a number of people down there, and their interests we are very careful in watching. Now, as regards the gross profit, that includes the profit on the sale of some of the securities we held last year.

A SHAREHOLDER: Is there any objection to give the separate amounts?

The CHAIRMAN: Yes, there would be an objection. We are a trading company, and there would be an objection to giving details. We have sold some securities during the past year, and that explains the difference between the items last year and this.

Mr. LAMONT: I suppose our steamers are not very useful for ordinary commercial purposes. It seems a pity otherwise that four steamers should lie idle earning nothing. There is another point. We all know how soon machinery becomes antiquated nowadays; but do you consider that the allowance of £13,000 keeps machinery quite up to the mark at the present day?

Mr. MATTHEW GRAY (Managing Director): In reference to our ships, I may say that they are not suitable for ordinary cargo ships. They are fitted up with cable machinery, and are filled with tanks, so that to take these out and make them suitable for cargo ships would be very expensive; and it would be very expensive to replace them and fit them up. We have been very anxious to utilise the steamers as far as possible, and we tried one voyage. The result was that we lost nearly £2,000. We got nothing for the hire of the ship, and we lost nearly £2,000, with all the care we could take. In reference to the machinery down at the works, I may say, with the utmost confidence, that the machinery is in first-rate order. I think any of the shareholders who may go down to the works, if they have any knowledge of machinery at all, will at once see that everything is in very good order indeed. I could not control the thing at all if we had not the first-rate workshop and workpeople we have. They are at least second to none in the country, I do not care where they are.

The motion was then put and carried unanimously.

The CHAIRMAN: It now devolves upon me to propose the re-election of two of our directors, Mr. Scott and Mr. Henderson.

Mr. GRAY: I have much pleasure in seconding that.

The motion was also carried.

Mr. LAMONT moved the re-election of Mr. Weise, the auditor, at a fee of 30 guineas, and said: I think at this time last year some remark was made as to the character of the certificate given by the auditor; but I see that this year it is about as full as could be expected.

General TREVOR: As I was the gentleman who wished on that occasion to have a more full certificate, I have great pleasure in seconding the proposition.

The auditor was thereupon re-appointed.

A vote of thanks was passed to the Chairman and Directors, and the meeting then closed.

NEW COMPANIES REGISTERED.

THE RIVER PLATE ELECTRICITY COMPANY (LIMITED).—Registered by Ashurst, Morris, Crisp and Co., 6, Old Jewry, London, E.C. Capital £500 000, divided into 49,900 shares of £10 each, and 1,000 shares of £1 each. Object, to enter into and carry into effect the agreements made with Walter Richard Cassels, and with the Rosario Electric Lighting Syndicate, to generate, produce, and deal in electricity or electric force for lighting or other purposes. The first directors shall be appointed by the subscribers to the Memorandum of Association, and shall each hold at least 50 ordinary shares in the capital of the company. The remuneration shall be the sum of £1,000 per annum, and one-tenth of the surplus profits remaining after payment of 10 per cent. per annum.

CITY NOTES, &c.

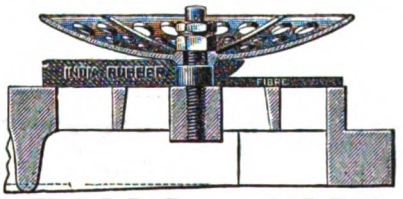
BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended February 8th amounted to £4,871.

SUBMARINE TELEGRAPH COMPANY.—The accounts for the half year ended the 31st December, 1888, enables the directors, after adding 15 per cent. of the gross receipts to the reserve fund, to recommend a dividend at the rate of 16 per cent. per annum, which compares with 15½ per cent. a year ago.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended February 8th, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,772.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 562.—Vol. XXII. FRIDAY, FEBRUARY 22, 1889. Price Fourpence.

NOTES.

The Court of Appeal delivered judgment on Monday last in the case of the Edison-Swan Company *versus* Holland and others, reversing the decision of the Court below and upholding the Edison patent. The Anglo-American Brush Company who appeared at the trial as "third parties" were condemned in costs, but the Court refused to issue an injunction against them or to order an inquiry as to damages, drawing a distinction between "third parties" and defendants in the suit. The result appears to be that the Edison-Swan Company would have to bring a fresh action in order to prove infringement of the patent by the Brush Company, but, as will be seen from the note below, this would involve some rather singular consequences. Meanwhile, we learn that the Brush Company has already given notice of their intention to appeal to the House of Lords.

It may have occurred to some of our readers to wonder why the Edison-Swan Company did not serve a writ upon the Brush Company in the first place, instead of attacking them through their customers. But thereby hangs a tale. The facts are these: Some time before the present action was commenced the Brush Company thought it would be wise on their part to secure the services of the three eminent counsel—Sir Richard Webster, Mr. Aston, and Mr. Moulton, and accordingly retainers were duly offered and accepted. Shortly afterwards the Edison-Swan Company—who were evidently alive to this transaction—entered their action against Holland, and the same three above-named eminent counsel—Sir Richard Webster, Q.C., Mr. Aston, Q.C., and Mr. Moulton, Q.C., knowing nothing of Holland, accepted retainers on behalf of Edison-Swan. When, therefore, the Brush Company, in spite of the opposition of the plaintiffs, succeeded in being made "third parties in the action," the three aforesaid eminent counsel found themselves in a decidedly queer position. The Brush Company was by no means willing to relinquish its claims upon their services—neither were their opponents. However, an understanding was eventually arrived at on this point of etiquette, and in the action against Holland the three eminent Q.C.'s appeared on behalf of the plaintiffs. But now comes the rub: If the Edison-Swan enter an action against the Brush Company to prove infringement and obtain damages, then the three eminent counsel who have hitherto so ably championed their rights will be found on the side of the alleged infringer! In such a case we should be prepared to witness a display of forensic ability of a most interesting, not to say entertaining, character.

Mr. Kennelly is to be congratulated on the very interesting and unique problem which the trouble on the Halifax cables has presented for his investigation, and we may add that there are not many electricians who would have grappled with its difficulties so successfully and thoroughly as Mr. Kennelly. The Paper read last night before the Institution of Electrical Engineers furnishes an admirable example of scientific method, and merits the careful attention of every student of submarine telegraphy.

A short time ago Mr. F. H. Blakesley read before the Physical Society an important Paper "On Some Facts Connected with the Systems of Scientific Units of Measurement." Mr. Blakesley "thinks it will be conceded that even the most hardened physicist feels some pangs of passage on the troubled sea of transformation from the *terra firma* of the electrostatic system to that of the electro-magnetic;" and we print further on the formula by which he proposes to effect the transition with the minimum of anguish. Mr. Blakesley, however, further points out that by making "v" the unit of velocity, the two systems would coalesce. This is only 30 times the present unit of velocity in the practical system, and it would merely involve making the unit of length 30 quadrants, or else the unit of time would be only $\frac{1}{30}$ second. He has also made the curious discovery that the reciprocal of the specific heat of air under constant pressure (·2382) is very approximately equal to 4·2, which is the well known numeric in Joule's equivalent, or the number of 10^7 ergs required to raise one gram of water 1° C. If, therefore, we take air instead of water as our standard of specific heat, we shall get the dimensions of temperature in terms of centigrade degrees expressed as a decimal number; in fact, 1° C. = 10^7 of one C.-G.-S. (air) unit. The author discovers some other curious numerical coincidences which it would certainly be well to recollect whenever we make up our minds to a reform in the present cumbersome system. As Mr. Blakesley remarks, this system is already twenty years old, and it is scarcely surprising to find that it does not fulfil all the wants of the present day. The Paper, which is full of interesting points, will be found in the *Phil. Mag.* for February. We cannot resist quoting the concluding passage as follows:—

"Dr. Whewell entertained a speculation as to whether the laws of motion would ever have been discovered by an intellectual race of jelly fish inhabiting a world in which were no social bodies. In like manner we may imagine that had Torpedoes, or other animals armed with a controllable electrical equipment, won the race for supremacy against man, the laws of electricity might have been reached before the mecha-

Digitized by Google

nical laws. Faraday and Maxwell would have preceded Galileo and Newton, and Gymnotus might have exhibited in submarine air-cases that uncanny biped Homo who could give you a curious and mysterious shock with a stick or a stone."

THE measurement of "v" by Sir WILLIAM THOMSON and Profs. AYRTON and PERRY, communicated to the British Association at Bath, was too small (292), on account of the accidental omission of a correction regarding the effective area of the attracted disc in the absolute electrometer. We now learn that when this correction is applied their result is brought up to 298, which exactly agrees with Profs. AYRTON and PERRY's previous determination by another method in Japan. Prof. J. J. THOMSON's result is 296·3. It is understood that ROWLAND has found 299. The result of Sir WILLIAM THOMSON's latest observations, founded wholly on the comparison of electrometric and electromagnetic determinations of potential in absolute measure, is 30·1 legal ohms, or 31·04 Rayleigh ohms. Assuming, as is now highly probable, that the Rayleigh ohm is considerably nearer than the legal ohm to the true ohm, the result for "v" is 300·4 million metres per second. Sir WILLIAM does not consider that this result can be trusted as demonstrating the truth within $\frac{1}{3}$ per cent.

MR. KAPP'S Paper on Alternate-Current Machinery (read before the Institution of Civil Engineers on Tuesday last) was worthy of the high reputation of the author. The subject is one upon which Mr. KAPP'S combined practical and theoretical acquaintance is at present probably unequalled in the profession. We postpone any further remark until after the publication of the Paper and the discussion in the *Journal* of the Institution.

IT would be strange indeed if the country which was first to make use of OHM'S name to designate the unit of resistance, and which has profited by his great discovery probably more than any other, had not been invited to join in a movement to do the illustrious German honour in his own country. The memorial, in the shape of a statue, which is to be erected in the city of Munich, will, in any case, be a well-deserved recognition of the fundamental service which the discoverer of "Ohm's Law" has rendered to electrical science and industry. We mentioned last week that the Royal Society has taken the matter in hand; a large committee has been formed, and the warmth with which the proposal has been responded to already affords assurance that, so far as England is concerned, the memorial will be worthy of the man.

THE full report now to hand of Dr. STEPHAN'S speech announcing the acquisition of the Anglo-German cables by the German and British Governments mentions the sum of 6,300,000 marks as the price paid by the first-named Government for its proportion of the purchase, a similar arrangement having been entered into on the part of the English Government. Much satisfaction was expressed by the German Minister of Posts and Telegraphs at the bargain he had been able to make, and the probable conclusion of arrangements with regard to the Belgian and Dutch cables on a like basis. A substantial reduction of the tariff is promised, and additional means of communication foreshadowed at no distant date, connecting Germany with the chief shipping and mercantile ports of Great Britain.

IN strong contrast with the above, the French Government are still raising difficulties about the purchase of the Anglo-French cables, and it is reported that no reduction of tariff is contemplated on those lines, whether they are purchased or are superseded. The conduct of the French Minister is, from every point of view, most extraordinary, especially as a considerable amount of the Submarine Company's stock is held by French men, who, of course, are as much interested in a liberal settlement as are the English shareholders. It will be remembered that it was the French Government that expressed its willingness to renew its concession to the company, and we heard nothing then about its cables being worn out and incapable of carrying the traffic. The English Government interposed, declining to be a party to the further concession, but raising no objection, so far as we have heard, to the company's property being bought at a fair price. Hereupon the French Government discover that the cables are not worth buying, and threaten to let them be abandoned as old iron at the bottom of the Straits. No doubt the Governments of the two countries would be within their strict legal rights if they declined to use the old cables; but all the same it would be an act of confiscation for which there is no moral or practical justification, for in reality the cables are worth a good deal where they are, but would be worthless if taken up. It is to be hoped that on this question Mr. RAIKES may now display as much firmness in demanding fair play for the English Company as he did in obtaining fair play for the English public when the renewal of the concession was under discussion.

The Electrical and Industrial Exhibition which is to be held in the Bingley Hall at Birmingham during the months of August, September, and October ought to become the exhibition of the year so far as this country is concerned. Nor do we think that its prospects are any the worse by reason of the competition of the Paris show. Our New York correspondent has more than once informed us that we may this summer anticipate the visit of a very large number of American electricians, on their way to and from Paris, and no effort should be spared on our part to make the Birmingham Exhibition worthy of the attention of our American friends. So far as the local managers are concerned we are convinced that every possible effort will be made to ensure success, and the rest must devolve upon the exhibitors. We may add that the long list of "Patrons" is headed by the MARQUIS of SALISBURY. The schedule, so far as yet arranged, will be found in a further note.

WE have often felt a lamentable inability to do justice to the humorous side of science, and never more so than on perusal of an article which recently appeared in the columns of our enterprising contemporary, the *New York Herald*. The article in question is characteristically headed: "Experiments in Barnum's Menagerie. The Wolf Weeps, the Baboon Fights,

Digitized by Google

and the Seal Upsets the Scientists;" and purports to be the only true account of an "electriciding" expedition undertaken by a party of scientists. Barnum and Bailey's "greatest show on earth" was placed at their disposal, and thither the enthusiasts adjourned, armed with 42 Leclanchés and 100,000 ohms. The experiments began at 11 a.m., and continued until the setting of the sun. The demeanour of the various unique animals kept at this establishment when under the influence of the subtle current is there graphically described. "The seal," we are told, "didn't like it," while "the gnu, or horned horse, did not take kindly to science." The exact resistance of the oryx is, we are glad to learn, 7,010 ohms, while that of the nylghau is only 5,090. These are interesting results. The dog experiments, however, were especially valuable, as they show that electricity undoubtedly brings out any incipient hydrophobia in the canine system. One dog, our veracious chronicler tells us, "after having a moderate current passed through the base of the brain, and showing a resistance of 8,000 ohms, began to act queerly, and within half an hour showed such symptoms of hydrophobia that the keepers were compelled to kill him." The elephants, on the other hand, proved "the star attraction of the day," and actually enjoyed the sensation, and we can quite believe that "no odder sight was ever seen than an elephant, with mouth wide open, with one scientist holding a sponge on the huge tongue, and a second applying another sponge to the root of his tiny tail." After the experiments Dr. F. G. Welch, of No. 140, West Forty second-street, was heard to say, "We had too small an electric power. We should have had enough strength to have killed something," and with this bloodthirsty pronouncement the narrative closes.

West Indies and British Guiana Cable.—We learn that the cable between Punta Rassa and Kew West is now repaired.

St. George the Martyr Vestry.—At a meeting of this Vestry last week the committee's recommendation in support of the House-to-House Company's License was adopted unanimously.

Personal.—We are pleased to learn that Mr. Slater, representative of the Western and Brazilian Telegraph Company (Limited) in Brazil, has been made a Commander of the Order of the Rose.

Edinburgh.—The number of telegrams which passed through the Edinburgh General Post Office last year was approximately 4,000,000, being an increase of nearly 500,000 over the previous year.

Commission of Sewers.—At a meeting of this body on Tuesday last the report of the Streets Committee on electric lighting was again adjourned, it being resolved to take it at a special meeting of the Commission.

An Electric Lighting Contract.—The Mayor of Meaux (Seine et Marne) will receive tenders for the electric lighting of that town up to March 1. A copy of the existing agreement with the gas company will be sent to any electrical firm who asks for it. The town possesses a waterfall.

Patent Law.—Under the title of "The True Position of Patentees," Mr. H. Moy Thomas has published, through Messrs. Simpkin, Marshall and Co., a little book in which the patent laws and regulations at home, abroad, and in our colonies are explained for the information of English inventors.

Electric-Lighted Buoys.—Major Gregory and Captain Evans, of the Lighthouse Board, who lately completed an inspection of the system of lighting the buoys in Gedney's Channel, New York Harbour, by electricity, report it a complete success. It is, therefore, safe to assume that the system will be extended to other waters.

The "Gas Engineer's Annual."—This is a handsome publication of some 130 pages, containing a very complete directory of Continental, Colonial, and foreign gas companies, and a well-written series of articles on subjects of interest to gas engineers. The article on electricity we notice is a reprint of Mr. Preece's British Association address.

The Electric Sugar Fraud.—It will be some slight consolation to English shareholders in the New York Electric Sugar Refining Company to learn that all the persons implicated in the fraud, including Mrs. Friend, have been arrested in Michigan on the charge of obtaining money by false pretences. The prisoners will be taken to New York for trial.

Electricity and Snakes.—According to a German paper, electricity is being used in India to prevent the intrusion of snakes into dwellings. A couple of wires are taken round the house, which are insulated from each other and connected with an induction coil. When his snakeship attempts to crawl over these wires he receives a shock of electricity that either kills or frightens him into a hasty retreat.

Ipswich.—At the meeting of the Ipswich Town Council last week, on the recommendation of the Paving and Lighting Committee, the Council passed a resolution generally approving of the granting of the license which the Ipswich Electric Light and Power Association are about to apply for, to authorise them to construct and maintain electric lines and works, and to supply electricity within the borough.

Important Sale.—Messrs. Wheatley Kirk, Price and Goulty have issued a preliminary announcement of the approaching sale of the entire property of the Elieson Electric Company (Limited), including their British, Foreign, and Colonial patent rights, tramcar station, engines, boilers, dynamos, &c. The date of the sale will shortly be announced. Further particulars will be found in our advertisement columns.

Engraving by Electricity.—A process of engraving on glass and crystal by electricity has been communicated to the French Academy of Sciences by M. Planté. The plate to be engraved is covered with a concentrated solution of nitrate of potash and put in connection with one of the poles in the battery, and the design is traced out with a fine platinum point connected to the other pole. The results are said to be of marvellous delicacy.

Sofia.—As notified in our issue of January 18th, the Municipality of Sofia has decided to light the streets of the town by electricity. We now learn that the Ministries, consisting of 10 houses with about 20 rooms in each, will also be lit with the electric light. Tenders for that purpose will be received by the Municipality of Sofia up to the 13th April, and it is desirable that communications should be made in French or German if possible.

The Vevey-Montreux-Chillon Electric Tramway.—The following are the results of the working of this line up to the end of 1888:—Total number of passengers, 320,412; total receipts, 66,978fr. The company began operations on the 4th June with a regular service every hour in either direction. From the 12th August to the 16th September there was a 40 minutes' service commenced, and since the 17th September there has been a 20 minutes' service.

Singular Accident at Chicago.—An engineer was severely injured the other day in the engine room of a Chicago installation, owing to the sudden flying to pieces of a slate disc. An examination disclosed the fact that there was a flaw in the plate which served as an insulator between the armature and the commutator. The dynamo was speeded at 1,300 revolutions a minute, and the imperfect disc of slate parted under the centrifugal strain.

Electricity Applied to Mining.—At the twenty-second annual meeting of the South Staffordshire and East Worcestershire Institute of Mining Engineers, held at the Mason College, Birmingham, on Monday last, Mr. F. Brown read a Paper on the "The Transmission of Power by Electricity." Mr. Brown mentioned several instances of the successful application of electricity to mining both in this country and in America. An interesting discussion followed.

The South London Tramways Company and Electric Traction.—At the half-yearly meeting of the South London Tramways Company on Friday last Mr. Saunders, Q.C., asked

Digitized by Google

whether anything was being done with a view to the ultimate adoption of electric haulage. The chairman replied that the directors were quite alive to the question of employing electricity for haulage. Some unsuccessful trials had already been made, and the question of further experiments was now being discussed.

The Indian Telegraphs.—We understand that Mr. J. H. Lane has recently been appointed Director of Traffic in the Telegraph Department, Mr. Reynolds becoming Director of Construction. Mr. Luke, who has been officiating in the latter post, proceeds to Upper Burmah to inspect the working of the telegraph lines in that new province.—The *Indian Engineer* says that it is more than probable that the heads of the Telegraph and Postal Departments will be permanently established in Calcutta.

Presentation.—An interesting ceremony took place on Monday evening, February 18, at the offices of the National Telephone Company (Limited), Leeds. The staff and men of the Leeds district testified their esteem and respect for Mr. Ralph Newburn, their late manager, by presenting him with a gold medal and a purse of gold. Mr. Newburn has been in the service of the "National" nearly nine years, and during the past four years was manager of the Leeds District. The presentation was made on behalf of the staff by Mr. J. C. Chambers, General Manager of the Yorkshire District.

The Lighting of the Houses of Parliament.—A small steam engine and dynamo, capable of supplying about 120 lamps, have been erected at the Houses of Parliament, thus increasing the total number of incandescents in the building to 620. Seventeen of the additional lights have been placed in one of the reporters' writing rooms, and the remainder are supplied to the members' entrance lobby, staircase, and corridor. After Easter the light will probably be extended to the Commons' lobby, St. Stephen's Hall, the offices immediately adjoining the House, and several of the Ministers' and reporters' rooms.

The Anglo-American Brush Electric Light Corporation.—We learn that the above company has secured an important contract for the supply of about 40 sets of combined engines and dynamos of their special design, and have now in hand orders for nearly 50 sets of apparatus of this pattern. The design has met with much favour from the European Governments since its introduction, and has been largely adopted for lighting ships of war and other vessels. The Brush Corporation have also booked a contract for the application of their system of electric traction to an important tramway line in Spain.

Leamington.—At a recent meeting of the Leamington Town Council the town clerk read the Board of Trade circular respecting underground mains, remarking that it was a rather unsatisfactory letter for the Electric Lighting Company, which it placed in the awkward position of being unable to recover any accounts. The matter was referred to the General Purposes Committee. A letter from Messrs. Chamberlain and Hookham was also read at the same meeting, offering to terminate the electric lighting contract at an earlier date than that provided for by the agreement. This matter also was referred to committee.

A Useful Improvement in Electric Light Casing.—We have recently examined an improved method of crossing electric leads, enclosed in casing, which has been devised by Mr. Bathurst. In lieu of running one wire underneath the other in an improvised groove in the base of the casing whenever a branch is taken off the main leads, Mr. Bathurst employs a semi-circular grooved block of wood, which carries the crossing wire an inch or more above the other. The crossing is covered in, and if the block is made of porcelain it forms a handy place for a fuse. This is one of those simple little devices which contribute so much towards the success of domestic installations.

Telpherage.—We learn that the United Electrical Engineering Company has secured the entire patent rights in connection with telpherage. Several important contracts are already under negotiation, amongst which may be mentioned two lines in Cornwall for the carriage respectively of 1,000 and 500 tons of tin ore per week. Under the capable and energetic management of Messrs. Manville and Madgen (the Managing Directors of the United Electrical Engineering Company) we fully anticipate that telpherage will shortly occupy a prominent position in the development of the electrical industries. No one who is capable of forming an opinion on the subject can have any doubt that it affords one of the cheapest and most efficient means of transport for heavy material which yet exists.

The India-Rubber Trade of Brazil.—Last year 15,000,000 kilogrammes of India-rubber were exported from Brazil, and this year the yield is still better, though prices rule much lower. The following are the figures for the last five years:—

Year.	Amount.	Increase.
1883-4	10,463,000 kilos.	—
1884-5	11,885,000 „	13·5 per cent.
1885-6	12,835,000 „	8 „ „
1886-7	13,395,000 „	4·5 „ „
1887-8	15,766,000 „	17·5 „ „

Of the amount exported in 1887-88 10,110,008 kilogrammes went to the United States, and 5,280,644 kilogrammes came to Europe. During the first six months of 1888 no less than 6,262,105 kilogrammes, valued at 12,924,429 reis, left the port of Belem.

Appointment of an Inspector under the Electric Lighting Acts.—At the weekly meeting of the Watch Committee of Liverpool Town Council, on the 19th inst., a recommendation was submitted from the engineer suggesting the appointment of an electrician to supervise the details in connection with the electric lighting question. The matter was discussed at some length, and eventually it was adjourned until further inquiries may be made. An opinion was expressed that the duties of the new post might be performed by an official chosen from the corporation staff, but it was explained that any person who undertook the responsibility should be thoroughly versed in the principles of electricity. At a previous meeting a resolution was passed that the city engineer communicate with Mr. Shoolbred and report further as to the appointment of an electric inspector under the provisions of the Liverpool electric lighting license.

Birmingham Electrical and Industrial Exhibition.—Following is the schedule of the electrical section:—Section No. 1: Dynamos—Motors—Alternating-Current Transformers—Accumulators—Primary Batteries—Arc and Incandescent Lamps—Insulated Cables and Wires (submarine, subterranean, and ariel)—Switch-Boards—Meters and Measuring Instruments—Automatic Apparatus—Switches—Connectors—Carbons—Electroliers—Shades and Fittings; Plant for Dwelling Houses, Ships, Theatres, Public Buildings and Central Station Installations. Section No. 2: Complete Display of Electric Lighting, upon all known systems and combinations, working in series and parallel, direct and through transformers—all Systems for Electric Transmission of Power. Section No. 3: Telegraph and Telephone Apparatus—Phonographs—Electric Bells and Clocks; Electric Welding—Electric Smelting—Electrotyping—Electro Deposition; Telpherage Working, &c., and all kinds of Electric Machinery and Appliances.

The Visit of American Electrical Engineers.—The following letter has been addressed by the Secretary of the Institution of Electrical Engineers to Mr. R. W. Pope, the Secretary of the American Institute of Electrical Engineers:—

Dear Sir: The President and Council of this Institution having been informed by Mr. W. H. Preece, one of its Past-Presidents, that many of the members of your Institute will be visiting the Paris Universal Exhibition this year, and will probably also visit London, have instructed me to inform you that it will afford them the greatest pleasure to welcome those gentlemen, and in doing all that is in their power to render their visit to England agreeable and instructive. The Council will feel obliged if you will kindly inform me how many of your members they are likely to have the pleasure of seeing, and the probable time of their arrival in London. Mr. Preece was requested to anticipate this letter by telegraphing to you "The Institution of Electrical Engineers, of London, will welcome your members and will do all it can to further the object of their visit."—I beg to remain, Dear Sir, yours most faithfully, F. H. Webb, Secretary.

Visit of the Junior Engineering Society to Deptford.—On Saturday last a party of members of this society visited the Deptford Central Station of the London Electric Supply Corporation, permission having been kindly granted by the

Digitized by Google

directors. The party were met at the works entrance by the resident engineer, who conducted them round, and explained the many interesting and unique features of the undertaking. The huge buildings are rapidly advancing towards completion. In the engine house the smaller engines of vertical Corliss type, by Messrs. Hick, Hargreaves and Co., were seen in course of erection, and on passing to the boiler house immediately adjoining, the setting of the Babcock and Wilcox boilers was being proceeded with. An inspection of the electric installation for lighting the whole of the works, and which was started as soon after their commencement as possible, brought the visit to a close. Before the members dispersed a vote of thanks was passed, expressing the gratification which the visit had afforded them.

Barnet.—The *Journal of Gas Lighting* is responsible for the following calendar of the deplorable failure at Barnet:—Sept. 6, all lamps went out at 10:15 p.m. for some minutes; Sept. 12, the lamps were lit this night at 7:15 p.m., at 7:45 all went out, they were relit, but again went out at 8:25 p.m., and were not relit; Sept. 28, all lamps went out at 9:55 p.m., and remained so; Oct. 3, lamps not lit till 6:45 p.m.; Oct. 23, all lamps went out from 9:25 to 9:50 p.m.; Oct. 28, all lamps nearly out at 6:25 p.m.; Nov. 2, all lamps out from 5:40 to 5:50 p.m.; Nov. 4, all lamps out from 5:25 to 5:40 p.m.; Nov. 11, all lamps out from 7:25 to 7:43 p.m.; Nov. 13, all lamps out from 6:45 to 7:15 p.m.; Nov. 26, all lamps out from 6:37 to 6:45 p.m.; Dec. 1, all lamps out from 11:22 to 11:35 p.m.; Dec. 8, all lamps out from 6:35 to 9:20 p.m.; Dec. 9, all lamps out at 11:45 p.m., and remained so; Jan. 11, 1889, nearly all lamps out from 9:5 to 10:10 p.m.; Jan. 23, all lamps out till 9:5 p.m.; Jan. 28, all lamps out from 5:50 to 5:55 p.m.; Feb. 6, all lamps out from 7:10 to 10:15 p.m.; Feb. 11, all lamps out from 10 to 10:7 p.m.

The Westinghouse Converter.—Mr. R. Bellfield, of the Westinghouse Electric Company, writes from Pittsburg as follows:—"I enclose a photograph of a Westinghouse converter which has been running under very trying circumstances. You will notice it is placed under a water-pipe and entirely exposed to the weather, which during the past fortnight has been very changeable, thus causing the converter to be subjected to alternate frosts and thaws, the results of which are shown in the photograph. The converter has been running continuously day and night since it was erected, and shows no sign of being affected by its late treatment. You will notice that both primary and secondary wires, as well as the converter case, are thickly coated with ice, which shows to some extent the amount of water they have been subjected to. This is not a specially built converter for the purpose, but a standard one taken out of stock, and is not subjected to any more severe test than hundreds of its fellows stand in exposed situations every winter." The photograph enclosed with the letter shows the converter almost completely coated with ice, and with long icicles depending from it apparently some 2ft. in length.

Transition Formulæ Between the Electromagnetic and Electrostatic Systems.—In a Paper read by Mr. Blakesley before the Physical Society "On Some Facts Connected with the Systems of Scientific Units of Measurement" (to which we make further reference elsewhere in this issue), he writes:—

"I do not think a rapid answer could be given by many persons to the question, What is the value in C.-G.-S. electrostatic units of a current of, say, 33·3 practical electromagnetic units? Yet in following out the experiments of Dr. Hertz, with which Mr. Tunzelmann has made us familiar, such a calculation must, I think, be made. I will here give two formulæ, which will enable any magnitude given in one system to be brought into the other.

Let k = the exponent of l in electromagnetic system,
h = " " m " " "
n = " " l in electrostatic system,
q = " " m " " "
for any kind of magnitude brought into due correlation with others.

Then, to reduce between practical (quadrant-volt-second) units electromagnetic and C.-G.-S. units electrostatic:—

1 practical unit $= 3^{n-k}10^{10n-11q-k}$ electrostatic C.-G.-S.

To reduce between C.-G.-S. electromagnetic and C.-G.-S. electrostatic:—

1 C.-G.-S. electromagnetic unit $= 3^{n-k}10^{10(n-k)+11(k-q)}$ electrostatic C.-G.-S. units.

The 3 in these equations is meant as a sufficient approximation to the number 2·938, which is one-tenth of 'v' in quadrants per second.

I have myself not seen such reduction-formulæ elsewhere, and under the present system I think they may be found of use."

Electrical Stress.—Prof. Rücker, at the Royal Institution, on Friday evening last delivered a lecture, in which he discussed the effects of the introduction of electrified conductors into non-conducting or nearly non-conducting liquids. The subject has been studied by Faraday, Kerr, Quincke, W. Holtz, and others, but various difficulties had prevented some of the more striking phenomena being shown in experimental lectures. The lecturer and Mr. Boys last year devised a set of apparatus which made the exhibition comparatively easy. Faraday's magnetic lines of force could be shown by the aid of iron filings, but the corresponding experiment in the case of electrical lines of force in a liquid was more difficult, because the liquid was thrown into violent agitation and the solids used tended to cluster about one of the poles. These points were illustrated by experiment, and the lines of force were realised by means of powdered antimony immersed in ether. The tendency of the lines of force to become shorter and to separate the one from the other was also illustrated, and from this the fact was deduced that a body subject to electrical stress assumed temporarily a kind of crystalline structure. Kerr's and Quincke's experiments on the passage of polarised light through carbon bisulphide were then discussed. Kerr's experiments depended upon the fact that since the electrical stress was a tension along the lines of force and a pressure at right angles to them, a substance in which such a stress was produced assumed a semi-crystalline condition in the sense that its properties along and perpendicular to the lines of force were different. Light was therefore transmitted with different velocities according as the direction of vibrations coincided with or was perpendicular to these lines, and the familiar phenomena of the passage of polarised light through crystals might be imitated by an electrically-stressed liquid. These researches were exhibited with various modifications and extensions. Finally, the lecturer referred to some outstanding problems which had not yet been completely solved.

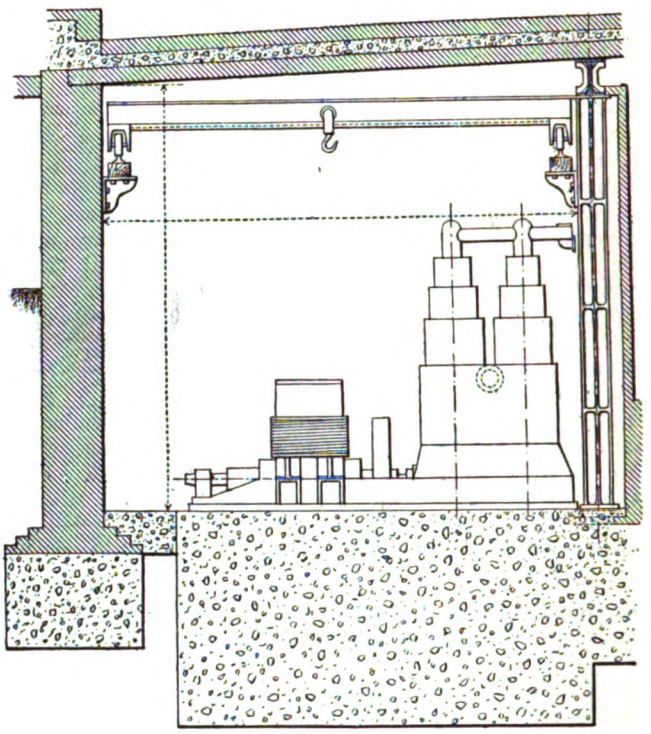
Gas v. Electricity.—The following extract from the speech of the Chairman at a recent meeting of the shareholders of the Gas Light and Coke Company will be read with interest:—"There is no doubt that the electric light is a very great comfort, and very beneficial to the public; but I say it does not compete with us, and I shall be able to give you some consoling figures in support of the assertion. I thought the best method of coming as near as we could to the value of the competition between a gas company and an electric light company was to take the part of London where there is more electric light than in any other locality—I mean the Bond-street district, where a great many shops, clubs, hotels, and public buildings are lighted by electricity. We have taken 325 of the consumers in the Bond-street district. Out of these 325 there are 29 who use the electric light. The gas-rental in 1885, when the electric light was introduced into Bond-street, was £7,527. In the year 1888, after three years' competition with the electric light in the Bond-street district, the gas rental, so far from falling, has increased to £7,836, so that, at any rate in that part of London, we have not suffered during the last three years very severely from electric lighting. Electric lighting, as I have said, is a very fine healthy child; but it is like other young children, it has troubles to come. A great many of those troubles are looming up in connection with the question of laying wires overhead and underfoot; and they will have their difficulties with the Vestries, as we have had. I do not know whether the steam-rollers will hurt them much; but there are other matters which the Vestries will find impede the use of the electric light in the streets of London. I do not think we shall hurt it; and I am sure it will not hurt us. We have taken 80 years to arrive at our position; and they will have a considerable number of years yet to exist before they will be in such a strong financial position. To compare our business with theirs is like comparing the business of a young man who has just started with that of an old gentleman who has accumulated a large fortune, and has a good going concern."

Digitized by Google

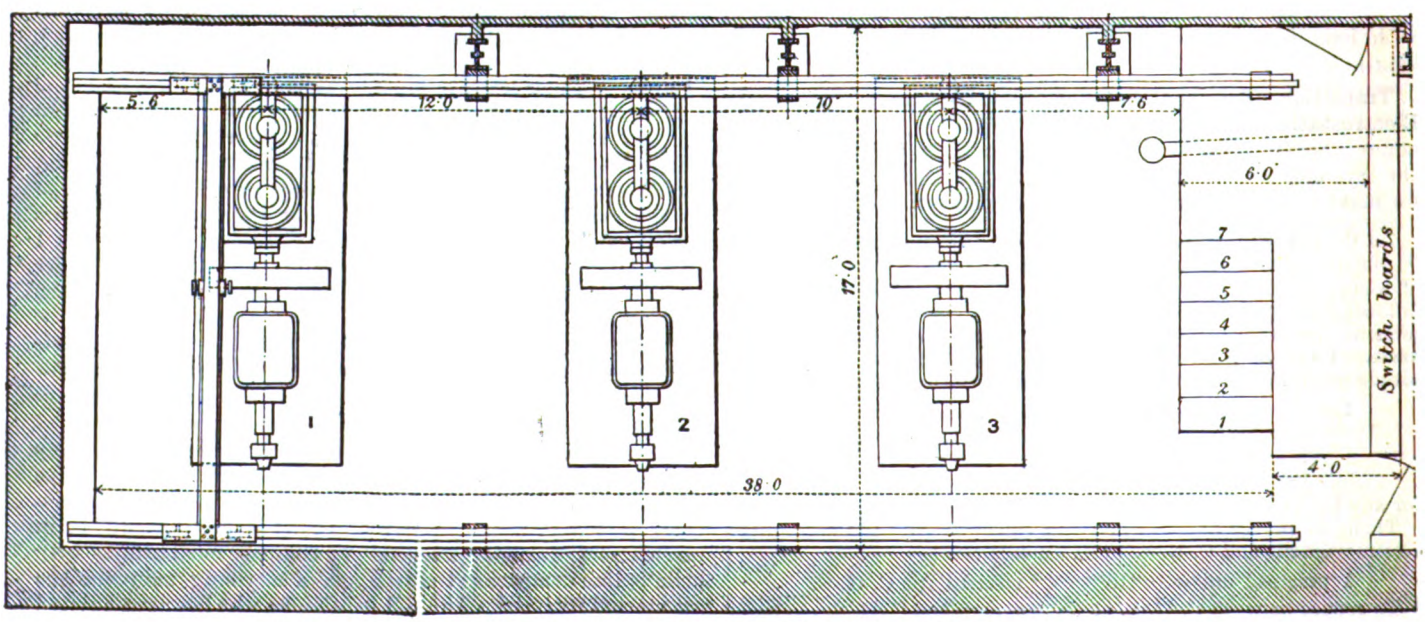
THE WHITEHALL CENTRAL STATION OF THE METROPOLITAN ELECTRIC SUPPLY COMPANY.

This station was originally undertaken in July, 1887, for the purpose of lighting Whitehall Court. It was impossible to find a site for the works, and therefore it was arranged to excavate the new road opposite Whitehall Court, and to place the machinery underground; but, as some of those in charge of the work foresaw the great development which electric lighting in the metropolis was likely to attain, a small company, known as the Whitehall Electric Supply Company, was formed to carry on the work, with all the usual powers for extension and enlargement. The success of the undertaking far exceeded the anticipations of the projectors, and the 10,000 lights which the station is capable of supplying were all taken up within a few weeks of the completion of the works. We may mention here that the standard lamp of this station is the 8 candle-power lamp run up to 10 candles. It was soon found that a far larger scheme than was at first contemplated would be necessary, and the Metropolitan Electric Supply Company was formed and took over the undertaking. The position of the works is admirably suited for the supply of current to the large clubs and hotels which form so marked a feature of the vicinity. Among the buildings lighted or about to be lighted from this station are the Grand Hotel, the Hotel Victoria, the Hotel Métropole, the Avenue Theatre, St. Martin's Church, Messrs. Hampton's large furniture warehouse in Pall-mall, and the Charing Cross Turkish Baths. In addition to these there is, of course, Whitehall Court, where, as gas is not laid on, a large demand for current may in time be expected. There can therefore scarcely be any doubt as to the future prosperity of the Whitehall Station.

The whole of the plant, comprising boilers, engines, pumps, condensers, dynamos and secondary batteries is underground, the road being carried on Lindsay's steel decking; and as the available room only amounts to 3,500 square feet, it is evident that considerable ingenuity must have been displayed in getting all this machinery into so restricted an area. The station is divided into four compartments. On the right of the entrance is the boiler-house, on the left are the pumps and condensers; passing on we come to the engines and dynamos on the right, and the battery room on the left. The dynamos are coupled direct to three fine vertical triple-expansion Willans and Robinson engines, running at 350 revolutions per minute. These engines each work up to 170 horse-power, and are run at present without electrical governors. The dynamos are by Messrs. Siemens Bros.; each of the three machines has an output of 100 kilo-watts (112 volts and 900 amperes) at 350 revolutions, and is of the latest type, with shunt-winding and drum armature. The secondary batteries, which number nearly 1,000, are of the Elwell-Parker 23L type, and are capable of giving in case of necessity 800 amperes for ten hours. The cells are arranged along the walls and down the centre of the battery room in four tiers, and as the battery room only measures 43ft. by 15ft. 6in. every available inch of space must have been made use of. The cells are connected in eight groups, each consisting of sixty in series and two in parallel. The E.M.F. at the lamp terminals is kept constant during charge and discharge by varying the number of cells in each battery, which is done by sliding switches. For charging a simple switch arrangement alters the 8 sets of 60 double cells into 10 sets of 48 double cells. Various kinds of measuring instruments are used at the Whitehall Station, the Cardew and the Schuckert voltmeters, and the Deprez-D'Arsonval galvanometers by Messrs. Nalder Bros. being preferred. The distributing mains are all laid underground down the roadways, in Callender-Webber conduits. In Northumberland-avenue, where the subway is available, all the cables are placed



Whitehall Station—Cross-section of the Engine and Dynamo Room



Whitehall Station—Plan of the Engine and Dynamo Room.

Digitized by Google

in strong wooden boxes, buried in the base of the subway. Some difficulty was experienced in carrying out the heavy work required in the subway, as, owing to the presence of gas mains, no naked lights were allowed, and the light of the ordinary safety lamps is insufficient to work by. This was overcome by lighting the subway from end to end by electricity by means of some 20 incandescent lamps. At present all the lamps supplied from the Whitehall station are charged for at 30s. per 8 candle-power lamp per annum for continuous lighting, and 25s. for supply from nine a.m. till midnight, but eventually, no doubt, the far more satisfactory system of meterage will be adopted. The boilers, three in number, are by Messrs. Hick, Hargreaves and Co.; they work at 160lbs. pressure, and each evaporates 3,500lbs. of water per hour. Each of them is 8ft. long, with 9ft. internal diameter, the shell being $\frac{15}{16}$in. thick. Two furnaces 2ft. 8in. in diameter and 5ft. 9in. long, are fitted to each boiler. The water is taken direct from the Chelsea Company's mains and passed into a "softener." This apparatus which is supplied by the Heater and Condenser Company, is capable of softening 1,500 gallons of water per hour. The water is taken by two boiler feed pumps and passed into the heater, and thence into the boiler. In the event of any interruption to the water supply, water could be obtained from the 40,000 gallon tank at the top of the building. The main flue is of somewhat peculiar construction, so peculiar indeed that it was predicted that no draught would ever be set up in it. On leaving the boilers it bends down and takes a 12ft. drop, it then bends again and passes at a gentle inclination under the foundations of Whitehall Court to the shaft. The great height of this shaft (135ft.) has, however, proved sufficient to ensure a good draught and falsify all the predictions of failure. The exhaust steam is condensed, the hot distilled water produced being used again in the boilers, and the condensing water being used to heat the hot water coils throughout Whitehall Court, and to supply all the baths and kitchens therein.

Some idea of the complication of the work may be obtained when we note that Whitehall Court consists of 10 floors and contains 120 sets of water coils, about 102 bath rooms, and some two or three hundred hot-water taps. Here, again, many predictions of failure were made, but the system, which is now complete throughout the north block of the building, was found to work perfectly on the first trial.

In summer, when not much hot water is used, a portion of the steam escapes uncondensed. This is carried up through a 15in. iron pipe placed in the shaft, so that the clean steam is discharged at the top of the chimney without causing smoke or any nuisance whatever. The pumps at the station are used to send the water up to the domestic supply tanks at the top of the building, the pressure on the mains being insufficient for this purpose. The 18 large hydraulic lifts of Whitehall Court will also be worked from the station, so that a considerable revenue will accrue to the company from this source alone. The elevator pumps also work the sixty-five fire hydrants in Whitehall Court.

The ventilation of the underground chamber presented peculiar difficulties, as it was part of the conditions of the lease from the Crown that no opening for ventilation or otherwise should be made through the roadway or the footway. Air is admitted from an opening, 10ft. by 12ft., in the area of Whitehall Court. A pipe, 5ft. by 18in., runs along the centre of the chamber close under the roof, and into this opening a number of 6in. pipes of various lengths are laid close to the roof in the channels of the Lindsay decking. The end of the square pipe communicates with the chimney, and a very good draft is obtained without interfering with the boiler draft. Although this draft works admirably in the present season, yet in preparation for the approaching summer, it has been thought wise to put in a small Sturtevant blower, driven direct by a small Willans engine, which is now being erected. This will be placed in the air inlet for the purpose of increasing the quantity of air in circulation. One noticeable feature of this installation is the perfect silence of the machinery. Standing, for instance, in the battery room, it is impossible to tell whether the engines are running or not. Nothing but a little clean steam is ever visible from the chimney.

Although neither the station arrangements nor the method of distribution present any great novelty, yet the admirable manner in which the many difficulties connected with an underground situation and so restricted a space have been overcome reflects the greatest credit on Mr. J. E. H. Gordon, who, with the able assistance of Mr. Frank Bailey, designed and carried out the whole of the work, including even the architectural drawings for the station.

The Metropolitan Company have now on order for London plant for 9,300 horse-power, capable of supplying over 200,000 lights. This is distributed between six stations, and the works are all being pushed on day and night with the utmost vigour, and it is expected that the whole of this instalment of lamps will be at work in the course of the next summer.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

"On Certain Phenomena Connected with Imperfect Earth in Telegraph Circuits."*

BY A. E. KENNELLY.

Since the earliest days of commercial telegraphy—the days that first reaped the labours of Sœmmering and Steinheil, Gauss and Weber, Cooke and Wheatstone—the substance of our planet has been impressed into such universal conducting duty that now scarcely a circuit closes, be it across an ocean or be it across a meadow, but embraces its share of the earth in its completion; and the task thus imposed is generally borne so readily and executed so perfectly that, until the existence of the eaves-dropping telephone, it was really doubted whether in truth the earth could or did conduct the current entrusted to its care.

Considering, then, the great obligations telegraphy owes to the earth—that the existence of some hundred thousand miles of metallic conductor at present in daily telegraphic operation implies in a certain sense the corresponding twin existence of an equal length of terrestrial conductor ready made by nature; that it has even been possible to telegraph over a space of which the metallic conductor formed but a very proper fraction—the cases that are met with where the earth fails to fulfil its part excite astonishment more by their rarity than by the force of those laws whose mandates they obey.

Almost all such cases of imperfect earth are, we know, traceable to some fault either in the earth connection itself or in its immediate neighbourhood; and a remedy is found by adequately increasing the surface area of the buried electrode, or the conductivity of the ground in its vicinity; so that they are not really failures of the earth's conduction, but failures in securing the necessary degree of connection with the earth's mass.

There are, however, other cases, brought about by conditions more deeply seated and more rarely met with, which will occupy our present attention.

A Paper by Mr. James Graves, "On Vibrations due to Earth Plates," was read before this institution in January, 1875, and it will be seen that the phenomena therein described are probably related to those that will be presently detailed. Although the matter has not occupied the institution's direct attention since that date, no doubt some of its members will have independently observed similar phenomena, and can bring forward such additional evidence as cannot fail to elucidate a subject at once replete with technical interest and important practical bearings.

These phenomena are presented by the Atlantic cables of the Direct United States Cable Company, with whose permission the facts are laid before the institution.

The two cables of this company, terminating in Nova Scotia, run to Ireland and to Rye Beach respectively. Their landing place was originally Torbay, N.S., but they were removed thence to Halifax some eighteen months since.

The diagram (Fig. A) supplies the outlines and main features of Halifax Harbour. The Irish cable was first brought into the cable-house, situated 40 feet above high-water mark, upon the beach opposite George Island, on the 23rd October, 1887, and it was put in communication with the town office by means of a line cable and a return earth cable, side by side, in an iron pipe. Each cable was 0·7 knot long, had a resistance of 8·3 ω, a capacity of 0·25 ϕ, and a high insulation. The line cable united with the Irish shore end through lightning guards, while the earth cable made good soldered connection with the shore end sheathing.

Some vibration of the mirror spot, due to electrical disturbance, was noticed on first joining up the circuit at the office through instrument and condensers, but this was at the time attributed to faults which then existed in the cable. Beyond this continual

* Paper read before the Institution of Electrical Engineers on 14th February, 1889.

Digitized by Google

vibration, no noteworthy feature occurred until six days later (29th October), when the Rye Beach cable was landed at the same cable-house, and joined up with the office by a precisely similar pair of cables running through iron piping in the same trench with the other above mentioned. This cable is worked on a double-current Morse system without condensers, and it was immediately noticed that sending to Rye Beach with 12 volts of battery power visibly disturbed the mirror spot on the Irish circuit, although each cable made earth separately through its own sheathing *viâ* the insulated return cables to the beach. Receiving from Rye Beach did not disturb the mirror, nor did the operation of the Irish cable in its turn affect the less delicate apparatus of the Morse circuit.

The only remedy that could be, or has since been, practically available without adding to the retardation of the circuits, was the reduction of the Morse battery power on one hand, and the sensitiveness of the Irish mirror on the other, as far as the operation of the circuits would conveniently permit.

After the removal of the faults in the Irish cable the vibrations of the mirror still continued, and it was noticed that not only these, but periods of disturbance coincident with local meteorological changes, affected the signals more than had been on record with the same circuit when worked previously from Torbay. On this was

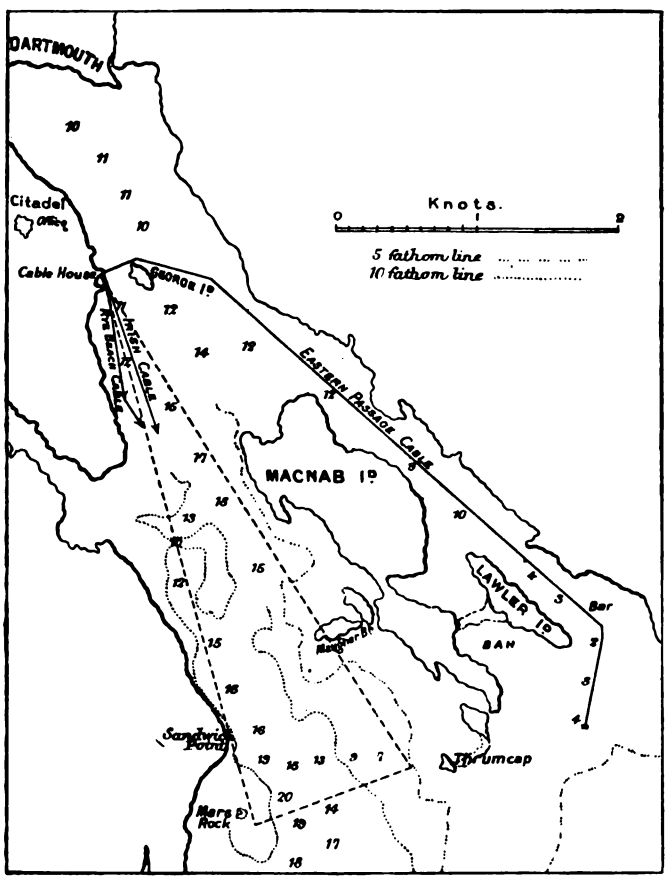


FIG. A.—Map of Halifax Harbour.

superposed the interference caused by transmission on the Rye Beach circuit, and the combined disturbance at times made the mirror signals difficult to read.

The Rye Beach shore end was at first laid very near to the Irish cable, and actually over it at one or two points. The cables were, however, subsequently separated, although they still necessarily lie at different points in close proximity. This separation of the cables was found to have sensibly lessened their interference.

The operation of the cables from the cable-house instead of from the office was found to produce no change in the nature or degree of disturbance, while experiment failed to produce any visible interference between the trenched cable circuits from office to Beach, even on the most delicate instruments.

A third cable was then laid from the cable house across the harbour, and out through the eastern passage in the direction shown on the diagram. It had a total length of 5·8 knots, sheathed up to within half a mile of the sea end. This unsheathed half-mile of core terminated in a copper earth-plate one yard square, nearly on a line between Thrumcap Rock and Hartland Point. This well-insulated line offered every prospect of securing a good and independent earth by its large terminal plate. When, however, it was joined up at the cable house with the Irish circuit, in the place of the Irish shore end sheathing, the interference from the Rye Beach transmission remained as marked as ever.

To determine the nature of this obstinate interference a series of experiments was made at the cable house as follows :—

All existing connections were for the time dismantled, and only the two cables, the two earth-wires soldered to their respective sheathings, and the core of the third cable, or six-mile earth, were brought up to the testing table.

The resistances between these three earth-wire terminals was measured as follows by bridge :—

Between Irish sheathing and Rye Beach sheathing 0·16 ω } all
,, ,, ,, ,, six-mile earth.....65·7 ω } steady.
,, Rye Beach ,, ,, ,, ...65·7 ω }

From which the resistance of each sheathing earth connection would, of course, be 0·8 ω, and of the six-mile earth 65 6 ω.

The only apparatus then retained for investigation was a Daniell battery of fourteen gravity cells—used with, and sometimes also without, a pole-changer—for exciting disturbance, and a sensitive speaking mirror—used with, and also without, condensers of 40 ϕ capacity—to render any interference visible.

Experiment 1. (*See* Fig. 1.)—Sending reversals from seven cells into the Rye Beach cable produced vibrations of the spot on the mirror instrument in circuit with the Irish cable, its sheathing, and 40 ϕ.

Experiment 2.—Similarly, sending reversals into the Irish cable, using its sheathing, produced vibrations on the mirror in circuit with the Rye Beach cable condenser and sheathing. (Fig. 2 is identical with Fig. 1, reversing the connection of the two cables.)

Experiment 3. (*See* Fig. 3.)—Sending reversals into the Rye Beach cable produced vibrations on the mirror in circuit with the Irish cable condenser and six-mile earth.

Experiment 4. (*See* Fig. 4.)—Sending reversals into the Rye Beach cable, using six-mile earth, produced vibrations on the mirror in circuit with the Irish cable condenser and its own sheathing.

Experiment 5.—Sending reversals into the Irish cable, using the six-mile earth, produced vibrations on the mirror in circuit with the Rye Beach cable condenser and its own sheating. (Fig. 5 is identical with Fig. 4, reversing the connection of the two cables.)

Experiment 6.—Sending reversals into the Irish cable, using its own sheathing, produced vibrations on the mirror in circuit with the Rye Beach cable condenser and six-mile earth. (Fig. 6 is identical with Fig. 3, reversing the connection of the two cables.)

Experiment 7. (*See* Fig. 7).—Sending reversals on the circuit formed by the six-mile earth, battery, and Rye Beach sheathing, the disturbance on the mirror in circuit with the Irish cable condenser and sheathing was more decided than in any of the preceding experiments.

Experiment 8.—Similarly, sending reversals on the circuit formed by the six-mile earth, battery, and Irish cable sheathing, the disturbance on the mirror in circuit with the Rye Beach cable condenser and sheathing was equally great. (Fig. 8 is identical with Fig. 7, reversing the connection of the two cables.)

Experiment 9.—The last two experiments were repeated with the condenser removed and the mirror in direct circuit between cable and sheathing. The continual vibration of the spot made observation difficult; but during periods of comparative quiescence it was soon determined that the disturbance produced by depressing one of the keys was not of a momentary nature only, but consisted of a small deflection, permanent during the whole period of key application, and of direction depending upon the key selected. It was also ascertained that this deflection was not due to any local electromagnetic action by

Experiment 10. (*See* Fig. 9.)—On sending reversals between the two cable sheathings in circuit with the battery, no disturbance could be detected on the mirror in circuit with one of the cables and the six-mile earth.

This small steady deflection produced by holding down the key in either of the two cases tried in Experiment 9 was more plainly visible when the mirror was in circuit with the Rye Beach cable, which, besides its shorter length, had no condenser in circuit at the distant station. To obtain some quantitative information regarding the strength of current represented, the fourteen cells were connected in series and more careful observations made.

Experiment 11. (*See* Fig 10.)—Closing the circuit formed by the fourteen cells, the six-mile earth, and Irish sheathing, measurements were made of the steady deflection so produced on the mirror joined up with the Rye Beach cable and sheathing.

The deflection obtained was subsequently found to approximately represent the two-hundred-thousandth part of an ampere—*i.e.*, 5 micro-amperes—and its direction was observed to be that indicating a current entering the Rye Beach cable from that pole of the battery which was connected to the Irish sheathing, reversing when the battery was reversed. Thus, in the figure the copper pole of the battery being shown connected to the sheathing, the deflection represented a current from the copper pole entering the Rye Beach cable through the mirror.

Experiment 12. (*See* Fig. 11.)—The Irish sheathing was replaced in the battery circuit by the water-pipe earth connection at the office through the trenched cable. On depressing the key the mirror showed the same permanent degree of disturbance as before in each cable circuit.

Experiment 13.—This experiment was a repetition of No. 3, with the condenser removed. It was subsequently observed in this case that the disturbance was not permanent during the depression of the battery key, but consisted of a small vibration of the spot at the opening and the closing of the battery circuit.

Experiment 14. (*See* Fig. 12.)—This was carried out at the office, situated in the principal street of the town, and nearly opposite to the Western Union Telegraph Office, fifty yards distant. All the Western Union wires are overhead, and the earth connections made for them are the gas and water mains, which, with the telephone lines, form the only metallic connection between the two buildings. With the courteous assistance of the Western Union officials it was arranged that at a given word by telephone several of their circuits should suddenly be operated, and again, all stopped.

When this was done the effect was distinctly visible upon a mirror in circuit with each cable, the disturbance being greater on the Rye Beach line, the earth connections being the cable sheathings through the insulated cables in the trench. Only four known causes could under any conditions produce interference between the two cable circuits, these being, of course, electrostatic induction, electro-magnetic induction, leakage, or bad earth connection in common; and, in the absence of evidence, any one or more might produce it, although no reason could be demanded for the operation of any, since cables lie in other parts of the world for greater distances at equal proximity without the least visible interference.

Experiment No. 10, together with the preliminary trials with the trenched cables, showed that the causes were not to be traced locally to these or to the apparatus; and the high insulation of the cables and circuits, together with the fact that the tests were carried out at the cable house, precluded all possibility of leakage being concerned, so that the operating causes were thus limited to the two forms of induction and bad earth.

The first six experiments did not directly point in favour of any particular cause, but Nos. 7 and 8 rendered the possibility of electro-magnetic disturbance untenable, since the exciting circuit, except in the cable sheathing itself, took a course, as seen on the map, almost at right angles to the two main cables. They further showed that the interference was such as a deficient earth connection would produce. Experiment No. 9 confirmed this view, since no form of induction could set up the steady deflections observed; and leakage being out of the question, bad earth was the only cause that could produce them. It was further necessary to suppose that not only one but both cable sheathings failed to secure good earth, and that the resistance in their respective earth connections was common to both.

Experiment 11 corroborated this position; and No. 12 did more, for it extended the limits of this bad earth region over the whole water-pipe area of Halifax, as it would have been impossible to obtain interference under those conditions unless the cable sheathings and the town water pipes formed a common conducting system throughout whose limits imperfect earth connection existed. Finally, the evidence of Experiment 14 followed the same direction, the exciting circuit being in this case the Western Union land lines.

The imputation of bad earth to the gas and water-pipe area of a town, and that town a seaport, is sufficiently remarkable, but the presumption of a general earth imperfection in a system of extended water and gas mains, together with the sheathings of three cables running directly into an arm of the sea, may at first sight appear an outrage upon credulity. Due consideration of the experimental evidence renders the conclusion, however, inevitable, and this is tantamount to the assertion that the whole of this system—that is to say, all the land covered by the town, as well as that forming the harbour basin—is composed of substance more or less insulated or insulating.

(To be continued.)

REVIEWS.

The Life of Sir William Siemens, F.R.S., D.C.L., L.L.D., &c. By William Pole, F.R.S. (Hon. Sec. of the Inst. Civ. Eng.) London: John Murray, 1888.

In the character of Sir William Siemens there were combined to an unusual degree very many of those conspicuous qualities for which the present century is chiefly distinguished, and, we may add—although Sir William was not himself of English birth—those qualities which have above all distinguished the English race. His engineering talent was of the very highest order, and he never shrank from grappling with problems of the first degree of magnitude and complexity in his own especial field. The pioneering work which he accomplished in Submarine Telegraphy, and in particular his designs for the "Faraday" cable ship, would alone have won for him a noteworthy place in the annals of engineering. As a man of science his knowledge was sound without being abstruse, and his investigations were chiefly directed towards practical utilitarian results. As an inventor his work is characterised by such originality, fertility of resource, and breadth of range, as it would be difficult to parallel. Unlike some modern "inventors," whose merit largely consists in their ability to attempt every conceivable combination for effecting the object in view, until by a process of exhaustion the most suitable device is arrived at, the inventive capacity of Sir William Siemens was directed and controlled by a clear conception of the conditions of the problem before him, and of the resources at his disposal for its attack. He was able, first, to fall back upon broad general principles, and then his keen practical instinct seemed to guide him almost unerringly to the details of their application.

Either singly, or in conjunction with others (chiefly his brother Werner), he secured no less than 113 patents in this country. They range over a vast field, and include steam engines, hot air engines, gas engines, water engines, cooling and freezing, evaporation and distillation, river engineering, the iron and steel manufacture, and other branches of metallurgy, gunnery, measuring apparatus, pneumatic tubes, glass making, armour-plating, telegraphs, electric lighting, electric power, and electric apparatus generally, in great variety, gas lighting, railway appurtenances, explosive compounds, and other miscellaneous matters.

As a man of business, his promptitude, energy, and capacity for work, were little short of marvellous. Combining, as he did, during many years of his life, the profession of a civil engineer with the occupations of a manufacturer and contractor on the largest scale, and in such diverse directions as that of telegraphy and iron smelting, he was yet able, by systematic attention to each in turn, to get through a vast amount of work of the most multifarious kind. In his later years the numerous scientific and other societies in which he held a prominent position made no small demand on his time, and he was a constant attendant at their meetings. The numerous Papers which he read before the British Association, the Royal Institution, the Royal Society, the Institution of Civil Engineers, the Telegraph Engineers (of which he was the first President, and, *de facto*, the Founder), and elsewhere, are marked by very considerable literary ability; indeed, they furnish admirable examples of the pure and lucid style in which scientific Papers *ought* (though unfortunately they are not) always to be prepared. This is the more noteworthy considering that English was to him an acquired language.

A life so full of enterprise and activity, and so intimately concerned with those great departments of human labour by which material civilisation is advanced, could scarcely fail to furnish matter for a story of the highest interest. But at the same time we are bound to recognise that the task of the Biographer now under review has been one of no small difficulty. To compress within the limits of some four hundred pages an adequate account both of the personal career and of the labours of Sir William Siemens could only have been accomplished by the sacrifice of a vast amount of available material. On the whole it would seem that the selection has been a judicious one, although it is possible that one class of readers may regret that a greater space is not afforded for personal detail, whilst another class would have preferred to learn more fully the particulars of his scientific achievements. In style, Mr. Pole's memoir is written with simplicity and straightforwardness, and, as need scarcely, perhaps, be said, with adequate knowledge of the *technique* of the scientific and engineering profession. Seeing, however, that a further opportunity of touching upon the scientific aspect of Sir William Siemens' career will shortly be afforded by the publication of his collected papers (now in the press), we shall confine ourselves, in the space still at our disposal, to a brief reference to some of the leading events of his life as recorded in the biography before us.

Digitized by Google

William Siemens was born near Hanover in 1823, his father belonging to the yeoman class of farmers. The children were ten in number, eight sons (of whom William was the fourth) and two daughters. At the age of fifteen his parents would have placed him in a mercantile house in Cologne, but Werner, who was seven years his senior, persuaded his father to allow him to take charge of his brother's future career, with a view to his training as an engineer. Under this arrangement William commenced the systematic study of the physical sciences, first at Lübeck, afterwards at Magdeburg, and finally at Göttingen University, and as he had already received a sound general education, he rapidly became proficient in mathematics, mechanical drawing, and mechanical and physical science as then taught. At this period the letters which passed between the two brothers, many of which are preserved in the biography, are full of interest, and testify to the affection which existed between them, and which only strengthened as years advanced. On leaving Göttingen William entered as a pupil the engineering factory of Count Stolberg, at Magdeburg, where he remained two years, carrying away with him a certificate which stated that he had been "industrious, trustworthy, and well-behaved," and had acquired "considerable facility in machine drawing." Meanwhile, at the suggestion of his brother Werner, in his spare time he had been making experiments on the deposition of gold and silver by electricity, and with so much success as to lead his brother, as well as himself, to believe that money might be made by the sale of the patent rights of the process which he had elaborated. England was considered to afford the most promising field for the enterprise, and at the age of twenty, in March, 1843, William Siemens arrived in London with a very limited supply of funds, and a vague idea that the British Government would examine the invention, and would reward him according to its merits. His knowledge of English at this period was by no means perfect, and the morning after his arrival he entered a shop in Finsbury-pavement under the impression that the word "Undertaker" over the doorway betokened the office of a functionary such as he was in search of. Once inside he was not long in discovering the mistake. Fortunately, however, he speedily fell into good hands, and left London for Birmingham with a letter of introduction to the already famous firm of Elkington Brothers. We have only space to add that when he left England a few weeks later the youthful inventor carried with him no less than £1,500, for which sum the Elkingtons had acquired his process. On his return his brothers and sisters hailed him as a veritable Croesus. A year later he was again in this country with an invention which he called the Chronometric Governor, upon which he set the modest valuation of £36,000. The easy triumph of the previous year was not, however, destined to be repeated, and a very long period elapsed before the chronometric governor—ingenious as it is—became anything like a financial success. Another invention of his earlier years, Anastatic Printing, was even less successful; both these projects cost Siemens many hours of anxiety, and for a time seriously handicapped his financial progress. More than once he seems to have almost lost heart, and at one period he even thought seriously of betaking himself to the California gold diggings. Fortunately the wise counsel and co-operation of Werner prevented the realisation of this rash idea. Meanwhile Werner himself had perceived something of the importance which the science of Telegraphy was destined to attain, and at the end of 1884 we find him writing to his brother:—

"I am now resolved to establish for myself a fixed career in telegraphy. This will become a special and important branch of scientific engineering, and I feel that I have a call to take up its organisation, as it is, I am convinced, yet in its infancy."

By the end of the following year the firm of Siemens and Halske had made a modest commencement—how modest may be gathered from the fact that the workshop occupied only one story of a building in which both the partners lived; but the inventive talent and scientific knowledge of Siemens, together with the mechanical skill of Halske, and the industry and integrity of both, from the first ensured success. It was in this factory that gutta-percha was first applied as the insulating covering of electric wires. In 1851 much larger premises were secured, and from that time forward their career was one of almost uninterrupted prosperity. Meanwhile William Siemens had undertaken to represent the firm in London; he had read a Paper on "Telegraphs" at the Society of Arts in 1851, and had arranged a large display of telegraph material at the Great International Exhibition of the same year. About the same time he became a partner in the Berlin firm, and the English branch was soon after established.

It is not our intention, even did space permit, to follow in detail the remainder of Sir William Siemens' career. From this time onward his attention was almost unremittingly devoted to the applications of electricity, and with what degree of success very few of our readers can need to be told. The volume is one which might be read with profit by every student of engineering science, for with the exception of his very earliest triumph—which was in part perhaps a happy turn of Fortune's wheel—it is plain to see that Sir William, and his brothers also, won their splendid successes by dint of sheer hard work, by undaunted perseverance, by continued attention to the lessons of experience, and by the exercise of a high sense of integrity, at least as much as by reason of exceptional intellectual ability.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To night) FRIDAY, February 22nd.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. "Some Considerations in favour of Gas-producing Furnaces in preference to other types." By T. A. GUYATT, Stud.Inst.C.E.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714.

All Communications to be addressed to "The Electrician," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician."

All letters intended for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.

"The Electrician" is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.

SPECIAL NOTICE.

Owing to the increase in the number of pages of "The Electrician," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For Foreign Parts and Colonies:— Within Postal Union	6 6	12 6	24 0

The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"The Electrician" offers exceptional advantages to Advertisers. **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Trade Advertisements *intended for the current issue must be handed in not later than First Post on Thursday morning.*

Small Prepaid Advertisements *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"The Electrician" Printing and Publishing Company (Limited) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "The Electrician" Electrical Trades' Directory and Handbook. The Directory was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.

THE DIRECTORY for 1889 is NOW READY.

"THE ELECTRICAL WORLD" IN THE UNITED KINGDOM.

Arrangements have been made by which "The Electrical World" of New York can be obtained from "The Electrician" Office, 1, Salisbury-court, Fleet-street, London, E.C.

The Rate of Subscription (payable in advance), including postage, is **£1 1s. 0d.** *per annum to this Country and Abroad.*

Single Copies of "The Electrical World" can also be obtained, **price 6d. each.**

The Rates for Advertisements in "The Electrical World" of New York can be obtained on application to "The Electrician" Printing and Publishing Company, Limited, as above.

"THE ELECTRICIAN" IN THE UNITED STATES.

Similarly, "The Electrician" can be obtained in America at the Offices of The W. J. Johnston Company, Limited *("The Electrical World"), 168 to 177, Potter-building, New York.*

"The Electrician" can also be obtained from The D. Van Nostrand Company, *23, Murray-street, and 27, Warren-street, New York.*

The Rate of Subscription for American Subscribers (payable in advance) is $6 per annum.

THE EDISON LAMP PATENTS.

Once more an Edison patent emerges triumphantly from the ordeal of litigation. The Lords Justices of the Court of Appeal, whose judgment we print elsewhere *verbatim*, are unanimous in holding that the decision of Mr. Justice Kay in the Court below must be reversed, and the Edison patent of November 10, 1879, is declared valid. It will be remembered that Mr. Justice Kay based his decision upon six separate points, which he described as follows:—

"My opinion is that the patent of Edison (No. 4,576, of 1879) is invalid; first, because the second claim is for a monopoly of incandescent lamps containing a filament of carbon for a burner, which claim, I think, is far too wide considering how little Edison had actually invented; secondly, because his specification does not describe a lamp which ever became, or, as I think, could have become, commercially successful; thirdly, because the directions therein contained are so insufficient that

"THE ELECTRICIAN"

Electrical Trades' Directory and Handbook

FOR 1889.

(Formerly "THE ELECTRICIANS' DIRECTORY AND HANDBOOK.")

This Electrical Directory and Handbook is not a mere unreliable List of Names and Addresses of Members of Various Societies, but contains Valuable Information for all persons engaged in Electrical Pursuits.

The Advertisers in "THE DIRECTORY AND HANDBOOK" are the Leading Firms of Electrical and Mechanical Engineers, Electric Light Contractors, Engine Makers, Electrical Apparatus and Supplies Manufacturers, and Firms engaged in the Allied Trades, and the book is, therefore, valuable for constant reference throughout the year. "THE DIRECTORY" can be ordered through any Bookseller or Newsagent, at the Railway Bookstalls, or at the Publishing Offices,

PRINCIPLES OF DYNAMO-ELECTRIC MACHINES.

PRACTICAL DIRECTIONS FOR DESIGNING AND CONSTRUCTING DYNAMOS. With an Appendix containing several articles on Allied Subjects, and a table of Equivalents of Units of Measurement. By CARL HERING.

The above work, just published, is the first American book on Dynamos, and the reputation of the author as a clear, concise writer on the subject of which it treats, is sufficient guarantee of the character of its contents. The book is copiously illustrated, printed on an extra good quality of paper, and neatly and substantially bound.

no one could have made the carbons he describes without considerable previous experiment; fourthly, because one of the processes described, namely, mixing the carbons with volatile powder, I believe to be practically injurious if done as Edison directs; fifthly, because the coating with a non-conducting, non-carbonising substance, if not injurious, is of no practical utility; sixthly, because the same may be said of coiling the filaments, on which the patentee lays great stress."

These several grounds for Mr. Justice KAY's decision were the more noteworthy because a similar suit had been instituted against the firm of Woodhouse, Rawson and Co. in 1886, when the Edison patent was upheld both in the Courts below and in the Appeal Court. Mr. Justice KAY was led to set aside the decisions previously delivered as having been obtained on insufficient evidence, the fresh facts brought before him seeming to justify that conclusion.

In view of the case being taken to a still higher tribunal, it may be worth while to examine the grounds on which chiefly the Appeal Court has reversed the decision of the Court below. These grounds are not so much scientific as legal—that is to say, on the main points Mr. Justice KAY, whether correct or not in his interpretation of the scientific evidence, was wrong in point of law. For example, Lord Justice COTTON maintains that "a patent is not to be defeated simply because subsequent inventions improved the patented article, or because in consequence of subsequent improvements no article was in fact made in accordance with the specification," a contention which seems to traverse the second of Mr. Justice KAY's reasons enumerated above. It may be observed, however, that the Court of Appeal is satisfied with the evidence that in fact incandescent lamps were made by EDISON in accordance with the original specification—a point obviously of much importance, and one about which there has been much conflict of testimony. It has also now been admitted by the plaintiffs that the carbon of the Swan lamp was formed into its final shape before being carbonised, an admission held to be fatal to one of the points relied upon in the former action. Some subsequent disclosures led to Mr. Justice KAY's dictum, with regard to the width and vagueness of EDISON's specification, being upset on appeal, although the point is, we fancy, more one of law than of fact. If the decision of the Court below was sound at the time, it would probably not be disturbed by the fact that Mr. SWAN's lamp was not a complete success, Mr. SWAN being now in a position which can scarcely tend to induce him to set too early a date or too high a value on his own invention. Two witnesses, strange to say, Messrs. PROCTOR and HEAVISIDE, asserted that he had invented and used carbonised cotton filaments in 1879; whereas Mr. SWAN himself fixes the time in the year following. He ought to know, and of course the Court held the other witnesses mistaken.

The judgment is equally adverse on Mr. Justice KAY's third point, that, namely, in which it was objected to the specification that it did not clearly show how the invention could be carried into effect. A great deal of contradictory evidence has been submitted on this question, some authorities holding that the various filaments mentioned could be made as described, while others were equally positive that they could not. The Judges seem to have believed that the latter could have done it if they had wanted to; but it is not easy for experts to enter on an experiment of that kind with perfectly open minds, and it would perhaps be just as fair to say that the experts on the other side could not have succeeded had they not known how to do it beforehand. Here again has arisen a nice point of law bearing upon the interpretation of the Patent Act, and it is one which may be decided differently by different Judges without the least reflection on their legal knowledge or impartiality. In the present instance the three Justices of Appeal have put a liberal construction on the Act, giving the inventor the benefit of the doubt, and in the interests of inventors generally this is a course which most people will regard with approval.

The fourth objection upheld by Mr. Justice KAY related to the coating of the filament with a non-carbonisable substance; but this was not of itself a very formidable objection; and as, like the rest, it has been overruled, we need not stop to examine it further. Lord Justice LINDLEY entirely concurred with Lord Justice COTTON; but his deliverance deserves to be carefully studied by patentees because of its lucid and masterly statement of the conditions to be complied with in drawing up provisional and completed specifications. It is needless to add that in his LORDSHIP'S opinion the Edison specification came within his definition of what is absolutely required in such cases. On the question of novelty, in which the Swan lamp crops up, Lord Justice LINDLEY put the matter in a way which is worth quoting as a point of some historic interest:—"One mode of trying this question," said his lordship, "is to ask whether any one would make such a thing as Swan's lamp 'F J B 1' if he took EDISON'S specification as his guide? I am convinced he would not; he would avoid and not reproduce Swan's carbon pencil, and would adopt Edison's type of carbon in the carbon filament." On his lordship's concluding observation relating to the new departure with which he credits Mr. EDISON a greater diversity of opinion may be expected. The new departure was not the introduction of carbon filaments, but the thinning of them down. The brief remarks of Lord Justice BOWEN are noteworthy chiefly for a very decided expression of opinion that "lamps made solely on the [original Edison] patent will and do succeed." This had been stoutly contested in the present action, and as the claim is now upheld the Edison lamp may be said to be once more completely rehabilitated.

DR. ARMSTRONG ON SOME FUNDAMENTAL POINTS IN THE THEORY OF ELECTROLYSIS.

[The following remarks by Dr. Armstrong have been appended to the third report of the British Association Committee on Electrolysis, "in order to direct attention to what he considers the uncertainty in which our conceptions of the fundamental phenomena of electrolysis are still enshrouded, notwithstanding the very definite assertions of recent foreign workers."]

There can be no doubt that the work done during the past year—which in many ways has been one of remarkable activity*—has tended more and more to favour the acceptance of the dissociation theory of electrolysis, that the conviction has been strengthened that electrolysis is primarily an affair of atoms; indeed, so far has this idea gained ground, that it is even argued by Arrhenius, whose conclusions are accepted by Ostwald and others, that in dilute solutions of hydrogen chloride, for example, as much as 90 per cent. of the HCl is dissociated into its ions. Prof. J. J. Thomson, in his recent work, "Applications of Dynamics to Physics and Chemistry," has, I think, very happily criticised this conclusion in the following passage (p. 213):—

"The reasons given for this conclusion do not seem to me to be very convincing, and the experimental results on which they are based seem to admit of a very different interpretation. The supporters of this theory urge that, for the salt to produce the effect which in some cases it does, it is necessary to suppose that the molecules of the salt exert a greater pressure than they would if they occupied the same volume at the same temperature when in the gaseous condition. This reasoning is founded on the assumption that all the effects due to the dissolved salt may be completely explained merely by supposing the volume occupied by the solvent to be filled with the molecules of the salt in the gaseous condition. Now, though we may admit that the salt does produce the effects

* *Cf.* Ostwald and Van't Hoff's *Zeitschrift für Physikalische Chemie.*

Digitized by Google

that would be produced by this hypothetical distribution of gaseous molecules, still it does not follow that these are the only effects produced by the salt. The salt may change the properties of the solvent, and the effects attributed to the dissociation of the molecules may in reality be due to this change."

Deville, who studied the behaviour of hydrogen chloride at high temperatures by means of his well-known apparatus with an internal cooled tube, observed only traces of dissociation at 1,300°, and Crafts and F. Meier could detect no appreciable dissociation in porcelain vessels at 1,500°, although in platinum at about 1,700°, according to Victor Meyer and Langer, it is to a considerable extent resolved into the component elements. That a gas of such stability should be almost entirely dissociated by mere dissolution in water is to me incredible.

Apart from actual electrolytic studies such as those of Arrhenius and Ostwald, the most important influence in forming opinion has been exercised (*a*) by Van't Hoff's masterly generalisation (*cf. Phil. Mag.*, 1888, 26, 81), to which Prof. J. J. Thomson is referring in the above-quoted passage, that the molecules of dissolved substances in dilute solutions exert the same pressure as they would if they were in the gaseous state at the same temperature and volume; and (*b*) by the introduction of Raoult's method of ascertaining molecular weights of dissolved substances by determining the extent to which they depress the freezing point of the solvent (*cf.* Chemical Society's *Transactions*, 1888, 610). While recognising the beauty of the conceptions, and while ready to admit that they may be applicable in many cases, my opinion is very much that expressed by Prof. J. J. Thomson. I agree with him that it is both possible and probable that a change in the constitution of the solvent is effected by the dissolved substance (*cf.* Chemical Society's *Transactions*, 1888, 125). The extraordinary effect on the properties of gold and copper, for example, of small amounts of certain foreign matters, so well known to electricians in the case of copper, and which has recently been brought prominently into notice in the case of gold by Prof. Roberts-Austen, may be cited in illustration of the kind of effect on the solvent which conceivably may arise.*

The arguments in favour of the dissociation theory appear, indeed, to be based on a narrow interpretation of the results; the dissolved substance alone is regarded as active, the solvent is neutral; the indubitable complexity of the phenomena of dissolution and of chemical interchange generally is entirely left out of consideration. Many chemists and physicists continue to regard values as simple constants, which there is the strongest reason to believe are composite. The law of the constancy of the so-called atomic heats of the elements is an illustration. It is well known that in the case of the majority of the elements the product of specific heat by atomic weight is approximately a constant. We are thereby enabled in many cases to determine *atomic* weights, but, be it noted, by a measurement effected with the aid of molecules, not of atoms. These molecules are undoubtedly of very varied atomic complexity, and it would seem that we are bound to assume that the nearly constant value of the so-called atomic heat is the outcome of a kind of balance—that as in raising the temperature of a solid work is done *inter-* and *intra*-molecularly, the amount of intermolecular work is greater in some cases and less in others, and the amount of intramolecular work proportionally less or greater, the amount per atom being, however, about the same in most cases. May we not interpret the simple results obtained by Raoult's method in a similar manner? Is it not probable that the effects are in reality often produced by molecular complexes of the *fundamental* molecules, the latter corresponding to the atoms to which we refer the result in discussing variation of specific heat with atomic weight? Perhaps it is only in cases in which *atomic* rearrangement has taken place that Raoult's method affords evidence of increased molecular complexity, as in the case of aldehyde and paraldehyde, for example, in such a case as that of dextrose, which, whether freshly dissolved or not, produces an effect such as is required on the assumption that its molecule has a weight corresponding to the formula $C_6H_{12}O_6$, there may be no atomic rearrangement but the mere juxtaposition of molecules involved in the formation of a "molecular" compound.

Arrhenius, Ostwald and others regard both electrical conductitvity and chemical activity as similarly conditioned by the degree of dissociation—in their opinion, very active substances, such as sulphuric acid, are to a large extent dissociated in solution; inert substances, such as acetic acid, are but to a slight extent dissociated in solution. But the adherents of this school all overlook the fact that there are two distinct theories of chemical interchange; the older theory that the interacting molecules initially combine and that the resulting complex then splits up—which may be termed the integration theory; and the more modern dissociation theory. I am led to regard the former as the more comprehensive and generally applicable, especially as comparatively so few compounds are electrolytes, and I venture to think that physicists also would incline more to my belief if they would assume a somewhat different mental attitude towards the facts, and would seek to fully unravel the entire series of changes involved in chemical interactions.

The attention of the committee has in previous years been directed to the question whether electrolytic conduction and metallic conduction are sharply separated from one another, and last year experiments by Prof. Roberts-Austen were described which appeared to show that alloys do not conduct electrolytically. Prof. J. J. Thomson deals with this question in his already-mentioned work in the following passage (p. 296):—

"There does not seem any necessity for supposing that the passage of electricity through metals and alloys is accomplished in a fundamentally different way from that through gases and electrolytes. For the chief differences between conduction through metals and through electrolytes are—(1) that in electrolytic conduction the components of the electrolyte appear at the electrodes, and we have polarisation; and (2) that the conductivities of electrolytes increase while those of metals diminish as the temperature increases.

"A little consideration will show that we could hardly expect to detect [polarisation] in the case of metals or alloys, for here instead of, as in electrolytes, the property of splitting up being confined to a few molecules sparsely scattered through a non-conducting solvent, the whole of the molecules can thus split up; thus the rate of disappearance of any abnormal condition would be almost infinitely greater than in the case of electrolytes, so that if any polarisation were produced it would probably die away before it could be detected. The only case in which we could expect to detect the appearance of the constituents of the conductor at the electrodes is that of the alloys, but even in this case Prof. Roberts-Austen was unable to detect any change in composition in the alloy round the electrodes. We must remember, however, that an alloy differs very materially from an electrolyte, because while in the latter we have a few active molecules embedded in a non-conductor, in the former it is as if the solvent as well as the salt conducted, so that the discharge is not concentrated on a few molecules of definite composition, but can travel by an almost infinite variety of paths.

"Then, again, the statements about the effect of heat on the conductivity of elements and electrolytes, though true in general, are subject to exceptions. Thus, the conductivities of selenium, phosphorus and carbon increase as the temperature increases, that of bismuth is said to increase at certain temperatures, and I have lately found that the conductivity of an amalgam containing about 30 per cent. of zinc and 70 of mercury is greater at 80 degrees than at 15 degrees. We must remember, too, that the rate of increase of conductivity with temperature for electrolytes diminishes as the concentration increases. No sharp line of demarcation can therefore be drawn between the two classes of conductors on this account.

"There does not seem any difference between metallic and electrolytic conduction which could not be attributed to the vastly greater number of molecules taking part in metallic conduction, whilst assuming that in all cases the current consists of a series of intermittent discharges caused by the rearrangement of the constituents of molecular systems."

I call attention to Prof. J. J. Thomson's remarks both on account of their suggestiveness and in order to point out that we are not in a position to make any such statement as the above regarding selenium, phosphorus and carbon. All observers hitherto have dealt with more or less *impure* substances—everyone, in fact, knows that the so-called carbon which conducts is not carbon at all in the true chemical sense. The conductivity of the substances in question may well be conditioned by the presence of the associated impurities, just as that of water appears to be, and hence their behaviour as electrolytes in respect of temperature changes; Shelford Bidwell's experiments with selenium distinctly favour this view. The differences between metals and non-metals are so great that the chemist has difficulty in resisting the conclusion that there is some very radical distinction to be drawn between metallic and non-metallic matter, although in practice it is impossible to say where metals end and non-metals begin. If it be found that the more nearly pure a non-metal is the greater is the resistance which it opposes, it will some day be possible, perhaps, to classify the elements into metals and non-metals on the basis of their electrical behaviour. In the hope of obtaining evidence on this point I have latterly been engaged in purifying selenium, with the object ultimately of determining its specific resistance; it appears highly desirable that "metalloids" such as arsenic and antimony should also be carefully examined from this point of view.

The increase in conductivity of bismuth and of Prof. J. J. Thomson's zinc amalgam at higher temperatures may well be due to a change in molecular composition, such as occurs in solid silver iodide, for example; both are cases in which the occurrence of such a change may be considered as probable. That molecular structure is an all-important element in influencing conductivity is all but established by the extraordinary diminution in conductivity effected by minute quantities of foreign elements in the case of copper, for example. In short, I am of opinion that as yet there is no experi-

* Prof. Roberts-Austen informs me that the melting point of gold is lowered to about that of zinc by $\frac{1}{10\frac{1}{2}\frac{1}{2}}$ of silicon

Digitized by Google

mental evidence to justify any modification of the time-honoured conclusion that electrolytic and metallic conduction are essentially distinct phenomena.

Considerable discussion has taken place during previous years in the committee as to the theoretical determination of E.M.F. on the lines originally indicated by Sir Wm. Thomson from thermo-chemical data, and attention has been directed to the necessity of taking into account reversible heat effects. I may be allowed to reiterate the opinion that the evidence tending to throw doubt on Sir. Wm. Thomson's law connecting the E.M.F. of a cell with the attendant chemical changes cannot as yet be regarded as in the least degree conclusive, and I venture to offer a brief criticism on the experimental work which has been done in this direction—chiefly by F. Braun (*Wiedemann's Annalen*, 1882, 16,561; 17,593) and by Wright (*Proceedings* of the Physical Society), who have measured the E.M.F.s of a large number of different cells, and have compared the values found with those calculated from the chemical changes which they *assume* take place in them. The calculated and observed E.M.F.s were found to agree in only a limited number of cases; in a considerable number the observed E.M.F. fell more or less below that calculated; in a few it was greater; and Wright has specially instanced a number of cells in which the current flows in the opposite direction to that which was to be anticipated.

The measurement of E.M.F. was made either by means of an electrometer, or with a galvanometer *using currents of very small intensity*; and there is no reason to doubt the results. But both observers were, as I have said, content to *assume* that the chemical changes were of a particular kind, and made no attempt whatsoever to study them in detail from the chemist's point of view.

Now it has been pointed out by Laurie (*Phil. Mag.*, August, 1886) that the extraordinary results obtained by Wright with aluminium zinc cells, which give an E.M.F. opposed to that calculated from the thermal data (of no less than 1 5 volt in the case of the sulphates), are to be accounted for on the assumption that he was not dealing with aluminium at all, but with *aluminium oxide* supported on an aluminium plate. It appears to me, then, that the whole of Braun's and Wright's results are open to this criticism, as the method of measurement which they adopted is one that would permit every surface impurity, every impurity in the agents—not excluding dissolved oxygen—to exercise its proper effect. Julius Thomsen has expressly recognised this source of error, and has pointed out the absolute necessity of measuring the E.M.F. of the element in full activity if it be desired to determine the full effect produced by the chemical interchanges which are involved in its action ("Thermoch. Untersuchungen," III., p. 487). On this account his comparisons of observed and calculated E.M.F.s may well be set against those of Braun and Wright; they are as given in the following table :—

—	Chemical Energy in heat units.		Observed Relative E.M.F.
	Absolute.*	Relative.	
1 { $Zn—H_4SO_4+100H_2O$ ... / $Cu—conc.CuSO_4,Aq$ ... }	50,130	1	1
2 { $Zn-H_2SO_4Aq$ .... / $Cd-conc.CdSO_4,Aq$...... }	16,210	·32	·32
3 { $Zn—HCl,Aq$ .... / $Ag—AgCl$ .... }	54,080	1·08	1·065
4 { $Zn—H_2SO_4+100H_2O$ ... / $Carbon—HNO_3$ .... }	96,080	1·92	1·86
5 { $Zn—H_2SO_4+100H_2O$ ... / $Carbon—HNO_3+7H_2O$.. }	82,810	1·65	1·69
6 { $Zn—H_2SO_4+100H_2O$ ... / $Carbon—CrO_3+SO_3,Aq.$ }	99,790	1·99	1·85
7 { $Cu—H_2SO_4+100H_2O$ ... / $Carbon—HNO_3$ ... ... }	45,950	·92	·88
7b { $Cu—H_2SO_4+100H_2O$ ... / $Carbon—HNO_3+7H_2O$.. }	32,680	·65	·73
8 { $Fe—FeCl_2,Aq$ .... / $Carbon—Fe_2Cl_6Aq$ ...... }	44,410	·89	·90

* To reduce heat units per dyad-gramme-molecule direct to volts use the divisor 46,000. The column headed "Relative" in the table would then run, 1·1, ·35, 1·18, 2·03, 1·80, 2·16, 1·00, ·71, ·97.

When it is borne in mind that in the case of nitric acid the products of change gradually accumulate and produce an effect, the agreement between theory and practice is remarkable.

Braun argues that "chemical energy" is of the form of heat energy, and that in its *conversion* into electrical energy in the cell there must therefore necessarily be some loss—some degradation; he terms that fraction of the total energy which takes the form of current the *electromotive efficiency* (Helmholtz's "Freie Energie"), and seeks to connect this with the dissociation temperature of the compounds formed at the electrodes. But if, to use Faraday's words, "the forces termed chemical affinity and electricity are one and the same," there is, I imagine, no *à priori* objection to be urged against Sir Wm. Thomson's law.

Braun has based a determination of the "electromotive efficiency" of a number of chemical changes on the assumption that the E.M.F. developed, for example, between silver, silver bromide, bromine and platinum, is to be regarded as developed simply in the formation from silver and bromine of silver bromide. The value found was 84, that deduced from the heat of formation is 91, so the electromotive efficiency is $\frac{84}{91} = \cdot 93$. The experiments were made in a very careful manner, and exceptional precautions were taken in purifying and drying the materials, the bromine used being purified by Staas's method. But the fact that the current *was* produced between silver, bromide and platinum, and between silver coated with silver bromide, bromine and platinum is, to my mind, sufficient to throw doubt on the results. It is impossible to prepare *pure* bromine, and it is a fair assumption to make that, if the materials had been pure, no current would have been observed. The determination of the E.M.F. is therefore of uncertain value: the number deduced cannot have been the outcome simply of the formation of silver bromide, as secondary change must have taken place to some extent.

I therefore venture to think that, up to the present, no experimental disproof of Sir Wm. Thomson's generalisation has been given; on the other hand, the fluctuations in E M.F. which accompany slight changes in composition—such as have been so clearly brought out by Lord Rayleigh's investigation of the Clark cell and by Wright's and Fleming's investigations of the Daniel cell—and also the influence which every change in the conditions exercises on the course of chemical change, would appear to favour the assumption that the electromotive efficiency of chemical change does not differ from the theoretical to the extraordinary extent that Braun suggests.

Before the temperature of dissociation can be taken into account as suggested by Willard Gibbs, we require to know to what extent this depends on the nature of the surface in contact with the dissociating substance.

It is also desirable that a clearer statement of the nature of the reversible heat effects should be given. I can picture to myself that on passing a current across a metallic junction the molecules became somewhat deflected from their original positions, or rotated, and that heat is developed on their subsequent return towards the normal position; but if this be the nature of the Peltier effect, and the converse action occur when thermo-electric currents are developed, it does not appear probable that the reversible heat effects at metal-liquid and liquid-liquid junctions would be of the magnitude to account for the extraordinary differences said to obtain in many cases between observed and calculated E.M.F.

LEGAL INTELLIGENCE.

Edison and Swan Electric Light Company v. Holland and Others.

Judgment was delivered in the Court of Appeal on Monday, February 18, in the case of the Edison and Swan Electric Light Company *v.* Holland and others (the Anglo-American Brush Electric Light Company, Limited, third parties), the judges being Lord Justice Cotton, Lord Justice Lindley, and Lord Justice Bowen.

Sir Richard Webster, Q.C., M.P. (Attorney-General), Mr. Aston, Q.C., Mr. Moulton, Q.C., and Mr. Bremner appeared for the appellants; and Sir Horace Davey, Q.C., M.P., Mr. Finlay, Q.C., and Mr. J. C. Graham for the respondents.

LORD JUSTICE COTTON said: This is an action brought against the defendants in respect of two patents, both of which were contested. The plaintiffs have sought to claim infringements of those patents. One of them was a patent granted to Cheesbrough. In respect to that Mr. Justice Kay decided in favour of the plaintiffs, and granted an injunction and consequential relief. As regards the other patent, which was one obtained by Edison, and dated the 10th November, 1879, he decided against the plaintiffs, and hence the appeal to us.

Now this patent has been before this Court before, and I had the advantage, or disadvantage, of being one of the members of the Court on the previous occasion. Then there was a difference of opinion between myself and the other Lords Justices as to the true construction of the specification, but I consider myself bound by the decision of the Court on that point, and in my opinion, except on questions of facts, which, of course, must be decided on the evidence in this action, the Court ought to consider itself bound by the previous judgment, which was in favour of the patent now vested in the plaintiffs—Edison's patent. In the previous case the Court held that there was no anticipation of the invention claimed by Edison, that it was a good subject matter for a patent, being for combination, many parts of which were not new, but which were rendered useful by a carbon bridge or burner, described as a filament, which the majority of the Court held not to be confined to the particular things described as filaments in the specification, but I think held that it must be substantially the same as regards these characteristics as the particular filaments described in the specification. The Court then decided that the utility of the invention was established. Here there was a great effort made to contest the utility of the invention. This was based principally on the contention that no successful incandescent lamps were made in accordance

Digitized by Google

with the specification of the 10th November, 1879, and without further improvements. The invention for the improvement of carbon filaments followed quickly on the patent of November, 1879, which greatly assisted in the manufacture and the utility of the burner of the incandescent lamp of November, 1879. That in my opinion was a useful combination; and a patent is not to be defeated simply because subsequent inventions improved the patented article, or because in consequence of such subsequent improvement no article was in fact made in strict accordance with the specification. But, in my opinion, it was established on the evidence that in fact incandescent lamps were made by Edison in accordance with the specification of November 10th, 1879, and were sent by him to Dr. Hopkinson, and publicly run by him in March, 1880. I do not see any facts now brought before us that ought to have induced the Court to depart, or to justify the Court in departing, from the previous decision of the Court on the question of the invention being useful, and being a good subject matter for a patent.

We then come to the objection of want of novelty, which is a question of fact. The only alleged anticipation which I need consider is that of Swan's lamp F J B 1, exhibited in December, 1878, and February and March, 1879, by Mr. Swan. In the previous case, on the evidence then before us, I thought this lamp was, on the construction put by the majority of the Court on the specification, an anticipation, but how does the evidence now stand? It is now admitted that the carbon burner of Swan's lamp was formed into its shape before it was carbonised, and this removes one of the points much relied upon by the plaintiffs in the former action. But we have now evidence, which was not before the Court in the former action, of what was being done by Mr. Swan and Mr. Stearn, after the experimental trial of this lamp. We have the evidence of Mr. Swan and Mr. Stearn. We have had before us the lamp F J B 1, and we have the letters written by Stearn to Swan in 1879 and in 1880, which were apparently read by counsel to show what was being done by Stearn and Swan. We see that that lamp was treated by them as a failure, and that their attempt to correct its defects led to lamps which differed more widely from F J B 1 than that lamp described in Edison's patent. This evidence assists the conclusion at which the Court arrived in the former action, that Swan's lamp in 1879 was not a success, and I think enabled me to come to the conclusion that this lamp was an experimental lamp which failed, and which was abandoned, and that the difference introduced by Edison was one which changed failure into success.

But it was contended by the respondents that, in fact, Swan had used for electric lighting incandescent lamps with carbonised thread burners before the 10th November, 1879. Two witnesses, Proctor and Heaviside, stated that carbonised thread lamps were in 1879 used by Swan. There is no ground for imputing dishonesty to these witnesses, but there was the direct evidence of Swan that he did not make any thread carbon lamp before 1880 or before the trial, the date of which is fixed at January, 1880; and I am satisfied that the witnesses were mistaken in fixing the date at 1879. Reliance was placed by the respondents on a lamp made by Bernstein, not an anticipation of Edison's patent, for it was not made until after 1879, but as showing that Swan's lamp was a practically useful one; but though Bernstein's lamp has a bridge or conductor or pencil of carbon like F J B 1, it has a different connection with the leading wire, which probably obviates some of the difficulties which prevented Swan's lamp from becoming a success.

Then I come to an objection which was much relied upon by the defendants, which was not raised in the former action, and which is now supported by a good deal of evidence. The objection, taken as a whole, was that the specification did not sufficiently show how the invention is to be carried into effect. It is necessary that this should be done so as to be sufficiently intelligible, and to enable the thing to be made without further invention, as was pressed upon us, not by an ordinary workman, but by a person described by Lord Ellenborough in Haddart *v.* Grimshaw as "a person skilled in the particular kind of work," or as described by another learned judge as "a person conversant in the subject." In my opinion it is not necessary that such a person should be able to do the work without any trial or experiment, which when it is new or specially difficult may frequently be necessary, however clear the description may be. One of the principal subjects of the attack was that part of the specification which gave directions for the making of a combination of lampblack and tar to form a material for the filament to be carbonised. Before the experiments, which by the direction of Mr. Justice Kay were made under the supervision of Prof. Stokes, the defendants' witnesses said that useful filaments could not be made out of this material, and Prof. Crookes was particularly strong in his ridicule of the idea that tar putty could be practically useful. Gimingham, a young man in the employ of the plaintiffs, produced and proved lamps with burners made of tar putty filaments, and after the experiments made before Prof. Stokes the defendants contended before us, without any support from the evidence, that the material could not be effectually prepared without a trade secret, which they said had only recently (that is, during the trial of the action) come to the knowledge of the plaintiffs, and probably had been communicated from America. It was said that this secret was the necessity of kneading the material for a length of time, and with the exercise of great pressure. In fact, Gimingham had for the trial of the previous action made lamps with tar putty filaments which were made exhibits in this action, and although there are no express directions in the specification how the tar putty is to be prepared, it is stated that the tar putty can be rolled into a thread as small as seven-thousandths of an inch, and I think it would be obvious to any intelligent workman who wished to prepare the material that it must be kneaded so as to make it perfectly homogenous and to prevent any breaking of the thread in consequence of any particle of lampblack not being perfectly amalgamated with the tar. I think that this objection fails.

But it was contended that lamps with tar putty filaments had not sufficient endurance to make them practically useful. No point was made of this before Prof. Stokes, so that no experiments were made to test this question. In fact, in the evidence before us many of these lamps are shown to have been run a sufficient time to prove that they could not be considered failures in this respect.

Another objection taken to the specification was that no sufficient directions were given as to the carbonisation of the filaments. The specification on page 3 says, "a cotton thread properly carbonised," and speaking of the thread of tar putty "this" (the tar) "may be carbonised in a closed chamber by subjecting it to a high heat," but no directions are given as to how this is to be done. Before the experiments made under the supervision of Prof. Stokes it was said that carbonising the filaments in a closed chamber without any packing, or with a packing of sand, which was suggested by Sir Frederick Bramwell, was impossible, as the filament would be reduced to ash. But this was proved to be unfounded, and before us it was still contended that no sufficient directions as to the mode of carbonisation were given. Carbonisation is a well known term, the ordinary process having been described as roasting without the presence of oxygen. This was well known and practised before the date of the patent, and Sir Frederick Bramwell in his evidence said that any person who knew the ordinary process of carbonisation would succeed in carbonising the filament. But it was strongly contended by the defendants and by some of their witnesses that such tender things as filaments could not be carbonised in closed chambers without being protected by packing, which the specification did not direct to be adopted. In fact, filaments were, as sworn by the witnesses of the plaintiffs, and demonstrated by the experiments made before Prof. Stokes, successfully carbonised in closed chambers or boxes without packing. Moreover, although the specification says nothing about packing, any skilled workman conversant with carbonisation would take the ordinary process of packing to exclude oxygen, and would, I think, know that when so delicate an article as a filament is to be carbonised the greatest care would be necessary to prevent any possible access of oxygen. It is true that there was no trade in carbonising anything so delicate as these filaments, but great care only in exercising a known process and applying it to an unusually delicate article was wanted, and no inventions would be necessary. When the defendants' witnesses failed in carbonising the filament, I think they did not use a reasonable care to exclude oxygen, as shown in their using porous crucibles. I am of opinion that this objection also fails.

Another point urged by the defendants was that the coating with a non-carbonisable substance described in the patent was injurious. The result of the evidence is that when the coating is a thin one the process can be and is done without any injurious result. But then it is objected that the specification did not direct a thin coating, and it was objected, and so held by Mr. Justice Kay, that this thin coating was a mere pretence of coating and dusting only. But it appears in the evidence of Mr. Crookes that he had himself adopted the same method of dusting as was adopted on behalf of the plaintiffs by this process. The process was I think in the specification proposed as preventing the filaments of the putty from sticking together during the process of carbonisation; and what I have said about Mr. Crookes I think shows that the process which produces the so-called "dusting" must be considered that which would naturally be adopted. I think that this objection also fails.

I have dealt with the principal points urged by the defendants, though shortly, in order to avoid the extreme length which would be necessary if I were to deal minutely with the various points. In my opinion the plaintiffs are entitled to judgment, and the appeal must be allowed.

LORD JUSTICE LINDLEY: The validity of the patent in question in this appeal is disputed on two broad grounds, namely: first, because the patentee has not particularly described and ascertained the nature of his invention; secondly, because he has not particularly described and ascertained in what manner the same is to be performed. The 9th Section of the Patent Act of 1852, under which the plaintiffs' patent was granted, imposes upon the patentee the necessity of complying with both of these conditions in order to sustain his patent, and the patent is bad if he fails to perform either of them. The two conditions, although often confused and overlapping, are really distinct, and it is always necessary to keep each clearly before one's mind, and not to commit the mistake of supposing that compliance with one is necessarily compliance with the other.

The first condition imposes upon the patentee the necessity of stating in clear and intelligible language what his invention really is, so that they may know, and that others may know, what addition the patentee says he has made to what was known before, so that they may know what they are not at liberty to do without his consent during the existence of the patent—in other words, so that they may know what the monopoly is that is granted to the patentee. The nature of the invention must be stated both in the provisional and in the complete specification; but whilst it is sufficient in the provisional specification to state the nature of the invention in general terms, it is necessary in the complete specification "to particularly describe and ascertain it."

The second condition imposes upon the patentee the necessity of stating in clear and intelligible language in what manner the patented invention is to be performed, so that others may learn from the specification how practically to avail themselves of the patented invention when the patent has expired—how they are to do what is necessary to carry out the new invention, the nature of which has been previously described. This condition applies to the complete specification only. There is no necessity for stating in the provisional specification how the invention is to be performed.

With reference to the degree of clearness and distinctness of the language necessary to be used in order to comply with these conditions, it is obvious that no hard and fast rule can be laid down. The degree of clearness could only be stated in language which itself admits of considerable latitude of interpretation. On the one hand, the patentee must make the nature of his invention and how to perform it clear and intelligible; on the other hand, it is not necessary for him to instruct persons wholly ignorant of the subject matter to which his

Digitized by Google

invention relates in all that they must know before they can understand what he is talking about. The patentee is adding something to what is known before, and he does all that is necessary as regards the language he uses if he makes the nature of his invention and how to perform it clearly intelligible to persons having a reasonably competent knowledge of what was known before on the subject to which his patent relates, and having reasonably competent skill in the practical mode of doing what was then known. In complying with the first condition—that is, in describing the nature of his invention—the patentee does all that is necessary if he makes the nature of his invention plain to persons having a reasonably competent knowledge of the subject, although from want of skill they could not themselves practically carry out the invention. In complying with the second condition—that is, in describing in what manner the invention should be performed—the patentee does all that is necessary if he makes it plain to persons having reasonable skill in doing such things as have to be done in order to work the patent what they are to do in order to perform his invention. If, as may happen, they are to do something the like of which has never been done before, he must tell them how to do it if a reasonably competent workman could not himself see how to do it on the reading of the specification, or on having it read over to him. The principle to be applied to the language used to comply with the two conditions is the same for both, and while one class of persons may understand only one part of the specification, and another class only the other, yet the patent may be valid. In a well-drawn specification the two conditions that have to be complied with are kept distinct, but in many specifications this course is not pursued. The nature of the invention and the manner of performing it are often described together. It may be that one set of words sufficiently discloses both the nature of the invention and the mode of performing it, but it may be, and sometimes is, very difficult to secure the two and say that both are sufficiently described. Still, if they are, in fact, sufficiently described, the conditions must be held to be complied with, however difficult and troublesome it may be to arrive at a conclusion.

I have been induced to deal at some length with the above matters because of their importance in the present case, and of the danger of losing sight of the principles by which the Court ought to be guided in deciding it.

I proceed now to inquire whether these two conditions have been performed, and I will take them in the order in which they logically present themselves. First, as to the nature of the invention. This Court has had to consider this matter before, and although there was a difference of opinion amongst the members of the Court, the decision of the Court was, as I understand it, first, that the expression "carbon filament," on which so much turns, was sufficiently clear and definite; second, that the nature of the invention was sufficiently described and ascertained, and was summed up in the second claim; third, that the second claim was in substance a claim to make a combination of a carbon filament with any receiver made entirely of glass, through which any leading wires pass, and from which air is exhausted; fourth, that the plaintiffs' carbon filament was essentially different from the carbon pencil used by Swan in his lamp F J B I, and that Swan had not by that lamp anticipated the plaintiffs' patent. The patent was upheld, notwithstanding the very large dimension of the second claim as construed. That decision is in my opinion binding upon us so far as the construction of the specification is concerned, but no further. I do not regard the decision as binding upon us upon the question whether the relative conditions to which I have alluded have been performed or not, for those questions depend not only on the construction of the specification but on the evidence as to the previous state of knowledge and as to whether a person of reasonable skill could at the date of the patent carry out the invention without further instruction than the specification gives him. I have, therefore, whilst taking the construction of the specification as settled, considered myself at liberty to exercise my own judgment on the effect of the evidence in this litigation. The construction of the specification which I consider binding involves three points, namely, first, that the specification is not too vague and unintelligible to be construed by the Court; secondly, that what is meant by a carbon filament is reasonably plain in the specification itself; and, thirdly, that the second claim, as construed by the Court, is not so wide as to invalidate the patent. The meaning of the expression "carbon filament" appears to me to be the crucial point for determination when we are dealing with the question whether the nature of the invention has been sufficiently described. This point, moreover, is in my judgment by far the most difficult in the whole case. Everything, I think, turns upon it. I consider it settled. I was no party to the decision, and the case will probably be appealed; but I think it desirable to state that, after much consideration and doubt, I have come to the conclusion that what is meant by the expression "carbon filament" can be gathered from the instances given in the specification, and that what is meant is any thread which can be made to bend in the required form, and can be carbonised when so bent. The thread, as shown by the examples, may be a fibre or a group of twisted fibres, or, as is to be got from the carbon of lampblack, it may be an artificial substance pressed or rolled into a thread or wire-like form. The evidence shows that as a fact the expression "carbon filament" was new as applied to electric lighting. Its meaning, or, in other words, the sense in which it is used by the patentee, must therefore be gathered from the specification. The sense in which the patentee has used the expression "carbon filament" can, in my opinion, be gathered from the typical examples given in the specification, and referred to in the judgement of Lord Justice Fry in the former case. The size of the filament is not stated, but it is quite clear from the objects to be attained that it must be long and thin, and nothing more definite is necessary to be stated. Having arrived at this conclusion, it follows that, in my opinion, the patentee has sufficiently described and ascertained the nature of the invention.

The next thing is to consider whether he has sufficiently described in what manner the same is to be performed. This is a pure question of fact and is in no way touched by the previous decision of this Court. Mr. Justice Kay has, however, found this against the patentee. Having carefully attended to the evidence and his judgment, I have come to the conclusion that I am unable to agree with him, and I cannot but doubt whether he would have arrived at the same conclusion if he had had the advantage, which we had, of hearing the Attorney-General's reply to the defendants. The defendants, in the first place, endeavoured to make out that carbon filaments could not be made as described by the patentee. The evidence on this point was so conflicting that Mr. Justice Kay called in an expert, Prof. Stokes, to assist him. This gentleman's report is absolutely conclusive in favour of the patentee upon the question whether carbon filaments can or cannot be made as described. On this point the defendants contend that no competent workmen could have made carbon filaments according to the specification without further instructions than are there given. If it be meant that few competent workmen could make them without some practice, I think the contention is well founded. But this is not sufficient to invalidate the patent. If a person is told to carbonise a thread, and for want of thought or practice he takes a porous crucible for the purpose, and does not protect his thread and fails, when, if he had packed his crucible, or had taken a non-porous crucible, he would have succeeded, his failure to carbonise can hardly be said to be the fault of his instructor, if a little thought and consideration would have shown him that a packed crucible or a non-porous crucible was the right one to employ. The fact that a workman might use a wrong tool when he has the right one, which a little thought would lead him to see ought to be used, does not warrant him to say that the specification is bad if it does not tell him which tool to use.

Again, with respect to the tar putty, the object to be attained is plain. The putty must be kneaded, so that it may be rolled out thin, without mark or flaw. Practice alone can teach any man how long and how hard he may knead; if he stops too soon and fails, is it the fault of the patentee? I should say certainly not. A similar observation applies to coating with a non-conducting, non-carbonisable substance. If the coating is made lightly by dusting all goes well, if too much is put on failure is the result. A little practice is all that is required. I feel the great difficulty of describing in words the distinction between an amount of practice without which failure is probable, but the necessity for which does not destroy a patent, and an amount of experiment and practice without which failure is certain, and the necessity for which destroys a patent. The test, however, by which to decide such a question is, I think, to be found by asking whether anything new has to be found out by a person of reasonably competent skill in order to succeed if he follows the direction of the patentee in his patent. If "yes" the patent is bad; if "no," good. So far as this point is concerned practice is one thing and experiment and trial are something different. Upon this point I have derived considerable assistance from former judgments of the late Master of the Rolls and other learned judges. It is settled that the patentee who does not disclose the best method known to him of carrying out his invention does not comply with the second of the conditions to which I have before referred; but if a patentee says that something must be done which a reasonably competent man would know how to do, the patentee need not tell how to do it nor warn him to be careful, and to exercise such forethought and attention as the delicacy of the process to be used or the material to be employed plainly demand. The evidence upon the question as to whether at the date of the patent a reasonably competent man could make carbon filaments without further instruction than is given in the specification or without further experiments was undoubtedly conflicting, and Mr. Justice Kay who saw the witnesses came to the conclusion that further instruction was necessary. The Attorney-General, however, convinced me that on that point Mr. Justice Kay was mistaken. I cannot myself come to the conclusion that the patentee has kept back any secret that he possessed by virtue of which he could in 1879 make carbon filaments better than any other persons could have done who followed the directions contained in his patent, and I think therefore that he is entitled to succeed. To ensure success, all that is necessary is carefully to follow the instructions there given, bearing in mind the objects to be attained and that the filaments are extremely delicate and can easily be destroyed. That is, in my opinion, a fair result of the evidence, and the fact that Edison in later years gave particular instructions as to the mode of carbonising, &c., only shows that he had then ascertained that those instructions were necessary to enable a competent man to obtain the desired results. It cannot, I think, be inferred that in 1879 special instructions were necessary to enable a reasonably skilful man to ascertain what the specification had failed to state must be done. The evidence on this matter is no doubt conflicting, but I cannot agree in thinking that the manner in which the invention is described is not stated sufficiently accurately for the purposes of the patent. If this were really true, it would have been found out long ago—at least, so far as carbonising is concerned.

There remain, further, two other matters for consideration, namely, novelty and utility. The novelty depends on whether Swan's lamp F J B 1 was an anticipation, but I am convinced that Proctor and Heaviside were wrong as to the date of the lamps made by Swan. The correspondence referred to by the Attorney-General is conclusive as to this matter. The lamp F J B 1 was held by this Court in the action against Woodhouse and Rawson not to be an anticipation of Edison's patent, but it was then supposed that the carbon pencil used in it was carbonised after and not before it had assumed its final shape. This was a mistake, and was admitted to be so in this action. The question of anticipation must be considered anew from the evidence before us. If Swan's lamp F J B 1 had been a success instead of a failure, it would, in my opinion, have been an anticipation of Edison's patent. The evidence, however, shows that it was a failure, and that Swan had not got the key to success. His own efforts to improve this lamp show that he was not thinking of filamentous incandescent carbons, but of other matters. Still his lamp did

emit light for a time, and was very near, although in my opinion not quite, an anticipation. It was in truth an unsuccessful experiment. I agree with Lord Justice Fry in thinking that "the point at which Mr. Edison's instrument departed from Mr. Swan's was crucial, and the departure, though slight, had all the merits of a new invention and produced a new result." Regarding the lamp F J B 1 as an unsuccessful experiment, this part of the case is governed by the principle laid down in a case reported in "7 Chancery Appeals." The question of novelty, which I am now considering, is closely connected with, although really different from, the question of whether the specification is sufficiently descriptive of the nature of the patented invention. Given the Swan lamp F J B 1, can it be said that the specification is descriptive of what is known at the date of this patent. Did he sufficiently describe the nature of what he added? In my opinion he did not in words distinguish his lamp from Swan's, but gave a description of a new type of body to be rendered incandescent, or, if I may use such an expression, a new type of wick. One mode of treating this question is to ask whether anyone would make such a wick as Swan's lamp F J B 1 if he took Edison's specification. I am convinced he would not. I believe he would not reproduce the Swan carbon pencil, but would try to get an incandescent light with carbon—that is, the carbon filament. The two may be made to shade off into each other until it becomes impossible to draw the line sharply between them. But this does not prevent a man from perceiving the difference between the two types, and from adopting the one which succeeds in preference to the one which fails.

There remains the question of utility. Edison's patent is said to be of no use, and the proof of this statement is said to be furnished by the fact that lamps are not made according to the patent by the patentee himself. The utility of the patent must be judged by reference to the state of things which then obtained. If the invention was then useful, the fact that subsequent improvements have been made, and rendered it obsolete and commercially bad, does not invalidate the patent. Such has been the fate of lamps made in the way described in Edison's specification. Such lamps appear to have been made and sent to him, but they were so soon improved that they at once ceased to be used in their original form. But lamps having carbon filaments in combination with the other essentials mentioned in the second claim are in constant use, and their utility is proved by the fact that this particular combination is used by the defendants, and by everyone, in fact, who makes incandescent electric lamps. The utility of the patented invention being established, the above combination is incontestible, and Mr. Justice Kay's opinion to the contrary is, I think, to be attributed to the view he took of the construction of the patent, a matter which, as I said before, I consider settled by the previous decision of this Court.

Before concluding I ought to notice the very formidable objection taken by Mr. Justice Kay to the validity of the patent, on the ground that the second claim is for a monopoly of incandescent lamps containing a filament of carbon for a burner, and that such a claim is far too wide considering how much Edison had invented. Whether the view here taken of the patent is correct or not turns, in my opinion, upon what Edison did when he introduced the carbon filaments. That was, I take it, a new departure of the highest importance in electric lighting, and if this be so the claim is not too wide.

For the reasons above stated I am of opinion that this patent, construed as it has been by this Court, is valid, and that the appeal ought to be allowed.

LORD JUSTICE BOWEN: In order not to add more than is necessary to the voluminous literature on the subject of this patent I will express my views as briefly as possible.

As regards the construction of the second claim, I think that we ought to follow the principle of what has been already decided by the majority of the Court in the case of the former action, but as I retain the same opinion as I then formed, the point becomes less material. The patent appears to me to claim in distinct and unmistakable language every combination of any carbonised filament with any receiver of glass through which leading wires pass, and from which the air is exhausted. Whether a claim so framed is too vague or too wide to be the subject of an independent patent, or whether it is wanting in novelty or utility, constitute an inquiry which, in my opinion, in part at all events, may be said to be bound up with questions of fact, and as far as all such points are concerned I think it desirable to judge this appeal *de novo* upon its independent merits. Construing claim 2 as embracing all combinations such as I have mentioned, is it too vague? I see no reason to doubt that in the year 1879 the term "filament," though new at that date as regards electric lighting, would nevertheless convey to the minds of ordinary persons of the class to whom this specification was addressed the idea of a slender thread, or thread-like substance, and it seems to me that the specification indicates that the thread or filament was first to be formed, and then to be subsequently carbonised. On page 2 of the patent the thread is distinguished from a rod. "Heretofore," says Mr. Edison, "light by incandescence has been obtained from rods of carbon. I have discovered that even a cotton thread properly carbonised will produce the requisite effect." The instances given in the specification which are enumerated in the judgment of Lord Justice Fry and myself in the previous appeal, and in the judgment of Mr. Justice Kay, are illustrations of the sense in which the term, which appears to me to be in itself intelligible, is used. The term "filament" is nowhere defined. It is a descriptive term, not a definition. But it appears to me to indicate the nature of the particular factor in the combination in a way that describes and ascertains the nature of the invention, so as to render it plainly intelligible to a skilled person of the class to whom the specification is addressed—language which embodies the old law, but which is tersely expressed in Lord Herschell's judgment in the case of Badische Anilin Fabric *v.* Leverstein, reported in 12 "Appeal Cases." The merits of a filament, as distinguished from a rod, are manifest. The filament, or thread, has an extremely small sectional area; it is flexible before carbonisation, and resilient afterwards. It is true that its merits are not explained, but I know of no law which renders it incumbent on the patentee in such a case to explain them. It appears to me, moreover, to be proved not only that every successful lamp since 1879 which is of avail for multiple arc lighting has employed a filament, but also that there is no proof that any filament cannot be adapted to the patented combination. If this is so, why is the claim too wide? That is not the fault but the virtue of the invention that it covers so large a field. We have been pressed with the argument that the Edison patent is useless, and that no lamp in the market has been made exclusively on the patent of 1879 without the aid of subsequent improvements. Improvements of real value followed with great rapidity on the patent which were actually utilised. Their rapid succession does not destroy the legal validity as regards the usefulness of the original combination to which such improvements were felicitously applied. The utility of this invention which was admitted in the Woodhouse case has been challenged in the present action, but I think unsuccessfully, and the evidence shows that lamps made solely on the patent will and do succeed, although subsequent improvements have been generally engrafted on the original design. Was F J B 1 an anticipation? We know now, what the Court did not know in the last action, that the carbon conductor of F J B 1 was formed before it was carbonised. Was it a filament? The question is one of degree. I doubt whether it is a filament, and I still more doubt whether any one who saw it would understand it to be such; but in any case I think F J B 1 was never more than an experiment, which was unintelligible, on account of its failure and barrenness of all fruit, and that it was regarded even by its inventor as practically valueless in the race. The correspondence between Messrs. Swan and Stearn shows, I think, to demonstration that till the middle of the year 1880 Mr. Swan did not consider himself to be upon the right track. The dates put forward by the witnesses Proctor and Heaviside seem to me to be unreliable and inaccurate, but I think there is reason for believing that it was Mr. Edison's patent which led back the world of electricians to the true path. Certainly, from the date of its exhibition that lamp F J B 1 disappeared from history until it was exhumed for the purposes of the trial in the Woodhouse case.

With respect to the remaining points used in the arguments before us I have nothing to add to what has been said by my brothers. I think this patent constituted a new departure in electricity, that the specification sufficiently describes and ascertains the nature of the invention, and that no reasonably competent operator alive to the delicacy and care obviously requisite in forming and carbonising so slight a thing as a filament ought, without any exercise of invention, but with reasonable watchfulness and only fair good will, to have been embarrassed in making and carbonising Mr. Edison's filaments. The appeal, in my judgment, should be allowed, with the usual results as to the costs; and I think I ought in conclusion to express my own obligation for the conspicuous clearness and ability with which this case has been placed before us at the bar.

On the application of the ATTORNEY-GENERAL the usual certificates as to the validity of the patent, costs, delivery over of the stock of infringing lamps on affidavit, and inquiry as to damages, were granted as against the defendants.

The ATTORNEY-GENERAL then referred to the position of the Anglo-American Brush Company, who had intervened as third parties, and had said they were the makers of the lamps, and would indemnify the defendants. Sir Horace Davey, in the Court below, had suggested that it would be more convenient that the Anglo-American Brush Company should be put in direct relation to the plaintiffs. He now desired to argue on the part of the plaintiffs before their lordships or some other Court, whether they were not entitled to have an injunction in this action as against the third parties. This was a case in which third parties would clearly be held to be estopped; and he was not sure whether the plaintiffs were not entitled to further relief. In the Court below the Brush Company had appeared, and throughout conducted the matter; they became parties to the action, and the issue was tried directly between them and the plaintiffs; in fact, the whole question of the validity and of the infringement was fought between the plaintiffs and them, and not between the plaintiffs and Jablochkoff and Holland.

LORD JUSTICE COTTON: I am afraid you are introducing a new practice not justified by the orders or the Act of Parliament. You cannot get an injunction except as against the defendants, their servants, and agents.
